SCRIPPS INSTITUTION OF OCEANOGRAPHY

POST OFFICE BOX 1529
LA JOLLA, CALIFORNIA 92093

Dear Colleague:

This document has been printed and distributed by the Deep Sea Drilling Project for the purpose of sample selection by interested earth scientists. Sample requests are honored after one year following completion of the cruise on which the samples were collected. It is an interim and informal document consisting of site data and sedimentologic and paleontologic data and interpretations as known six (6) months post-cruise. These data, while adequate for most sample selection needs, are subject to slight revision by the time of issue of the corresponding volume of the Initial Reports of the Deep Sea Drilling Project.

The information contained herein is preliminary and privileged, consequently this document is not to be cited or used as the basis of other publications. Data cited or used in a manuscript will be considered a breach of professional ethics.

Thank you for your interest in the Deep Sea Drilling Project.

Sincerely,

David G. Moore
Chief Scientist
Deep Sea Drilling Project

INITIAL CORE DESCRIPTION (ICD)

DEEP SEA DRILLING PROJECT

LEG 43

June 13, 1975 — August 12, 1975

A Project Planned by and Carried Out With the Advice of the
JOINT OCEANOGRAPHIC INSTITUTIONS FOR DEEP EARTH SAMPLING (JOIDES)

MEMBER ORGANIZATIONS

Lamont-Doherty Geological Observatory, Columbia University
Rosenstiel School of Marine and Atmospheric Sciences, University of Miami
Scripps Institution of Oceanography, University of California
University of Washington
Woods Hole Oceanographic Institution
Institute of Geophysics, University of Hawaii
School of Oceanography, Oregon State University
Graduate School of Oceanography, University of Rhode Island
Department of Oceanography, Texas A & M University
USSR Academy of Sciences, P. P. Shirshov Institute of Oceanography, Moscow
Bundesanstalt für Geowissenschaften und Rohstoffe, Hannover
Ocean Research Institute, University of Tokyo

PARTICIPATING SCIENTISTS

. B. Tucholke, P. R. Vogt, K. Demars, J. Galehouse,
R. L. Houghton, A. G. Kaneps, J. Kendrick, I. N. McCave,
C. L. McNulty, I. O. Murdmaa, H. Okada, P. Rothe

INITIAL CORE DESCRIPTIONS - LEG 43

INTRODUCTION

Leg 43 marked the return of the GLOMAR CHALLENGER to the western North Atlantic, an area that had remained undrilled since the earlier phases of the Deep Sea Drilling Project. Drilling during Leg 43 had three specific objectives: (1) to drill into the lower flanks of the New England seamounts in order to see if there is an age progression in volcanism along this chain; (2) to determine the nature of the oceanic crust beneath the J anomaly, a prominent high-amplitude magnetic anomaly that is locally observed at the young end of the Keathley or M-series of anomalies in the North Atlantic; and (3) to determine the nature and age of a series of seismic reflection horizons on the Bermuda Rise that are used for stratigraphic mapping in the North American Basin.

Six sites were drilled during Leg 43, two to fulfill each of these objectives (Figure 1). Lithology and Stratigraphy of the sites are indicated in Figure 2, and site data are given in Table 1.

Sites 382 and 385 penetrated the lower flanks of Nashville and Vogel seamounts, respectively and recovered upper Cretaceous volcaniclastic breccias that probably represent the last phases of volcanism at these sites. Unfortunately, poor paleontological age control in the volcanics does not allow any firm conclusions to be drawn about the relative age of volcanism at these two sites.

Sites 383 and 384 were drilled on the J anomaly, Site 383, on the Sohm abyssal plain, was terminated prematurely because of severe hole instability problems due to caving of coarse Pleistocene turbidite sands. Site 384 was drilled further north where the basement ridge that underlies the J anomaly rises above the level of the Sohm abyssal plain. Basement here is overlain by Aptian reef carbonates, an upper Cretaceous through lower Eocene calcareous pelagic ooze sequence, and a highly condensed Neogene section (uncored). Basement, on first examination, appears to be a rather normal diabasic basalt of mid-ocean-ridge affinities. Additional work will be needed to establish the origin of the J anomaly.

Sites 386 and 387 were cored to basement on the Bermuda Rise. The oldest sediments at Site 386 are black Aptian claystones, while at Site 387 the lowest sediments are gray lower Cretaceous limestones. Both sites reaffirm the now well documented Cretaceous stagnation phase that affected large portions of the Atlantic. They also show that the timing and duration of stagnant conditions were subject to local physiographic controls. Whereas the euxinic phase at Site 386 ended in the late Cenomanian, black clays at Site 387 continue well into the upper Cretaceous, with short intervals persisting into the Danian. Paleogene deposition on the Bermuda Rise was characterixed by rapid accumulation of siliceous muds and the Neogene by poorly fossiliferous silty clays.

The present volume contains descriptions of Leg 43 core materials. The core descriptions for each site are prefaced by a brief summary

of principal geological results. For a fuller discussion of Leg 43 results, reference is made to the report published in Geotimes (December, 1975, v. 20, no. 12). Leg 43 core materials become available for distribution to interested scientists on August 12, 1976. For purposes of sample selection it is recommended that the following section of explanatory material be read.

TABLE 1. SITE DATA.

Leg 43—drilling and coring summary hole	dates (1975)	latitude longitude	water depth (m)	penetration	no. of cores	oldest sediment	deepest unit
382	July 5-9	34°25.04'N 56°32.25'W	5,527	520.5m	25	Coniacian- Santonian	volcaniclastic breccia
383	July 10-12	39°14.88'N 53°21.18'W	5,277	120.3m	2	Pleistocene	sand
384	July 12-15	40°21.65'N 51°39.80'W	3,910	330.3m	22	Aptian or older	basalt
385	July 18-20	37°22.17'N 60°09.45'W	4,956	392.9m	24	Lower Maestrichtian or older	volcaniclastic breccia
386	July 24-31	31°11.21'N 64°14.94'W	4,783	973.8m	66	Upper Aptian- Lower Albian	basalt
387	Aug. 1-7	32°19.2'N 67°40'W	5,118	794.5m	50	Upper Berriasian- Lower Valanginian	basalt
			totals	3132.3m	189

EXPLANATORY NOTES

Introduction

Persons wishing to obtain samples are directed to the DSDP-NSF sample distribution policy (reproduced herein, p. 20). Sample requests must be submitted on standard DSDP request forms which may be obtained from:

The Curator
Deep Sea Drilling Project A-031
University of California, San Diego
La Jolla, California 92093

The following material is intended as an aid in understanding:

(1) the terminology, labeling, and numbering conventions used by the Deep Sea Drilling Project;

(2) the sediment classification and biostratigraphic framework used on Leg 42A; and

(3) the presentation of the lithologic and paleontologic data on the core forms which make up much of this publication.

Numbering of Sites, Hole, Cores, Samples

Drill site numbers run consecutively from the first site drilled by GLOMAR CHALLENGER in 1968; the site number is thus unique. A site refers to the hole or holes drilled from one acoustic positioning beacon. Several holes may be drilled at a single locality by pulling the drill string above the sea floor ("mud line") and offsetting the ship some distance (usually 100 meters or more) from the previous hole.

9

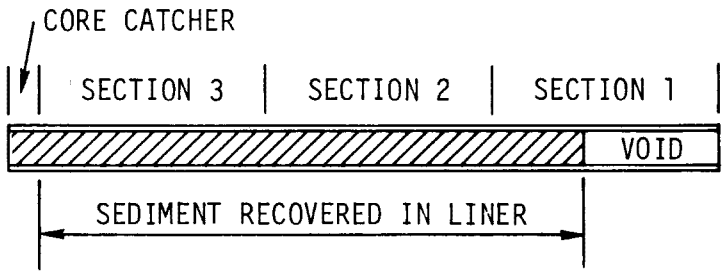
The first (or only) hole drilled at a site takes the site number. Additional holes at the same site are further distinguished by a letter suffix. The first hole has only the site number; the second has the site number with suffix A; the third has the site number with suffix B; and so forth. It is important, for sampling purposes, to distinguish the holes drilled at a site, since recovered sediments or rocks usually do not come from equivalent positions in the stratigraphic column at different holes.

Cores are number sequentially from the top down. In the ideal case, they consist of 9 meters of sediment or rock in a plastic liner of 6.6 cm diameter. In addition, a short sample is obtained from the core catcher (a multi-fingered device at the bottom of the core barrel which prevents cored materials from sliding out during core-barrel recovery). This usually amounts to about 20 cm of sediment or rock. During Leg 43 the core catcher sample was split, described, and stored along with the rest of the core, if at all possible, taking care to maintain its proper vertical orientation. This sample represents the lowest stratum recovered in a particular cored interval. The core catcher sample is designated by CC (e.g., 382-4, CC is the core catcher sample of the fourth core taken at Site 382).

The cored interval is the interval in meters below the sea floor measured from the point at which coring for a particular core was started to the point at which it was terminated. This interval is generally 9.5 meters (nominal length of a core barrel) but may be shorter if conditions dictate. Cores and cored intervals need not be contiguous. In soft sediment, the drill string can be "washed

ahead" without recovering core by applying sufficiently high pump pressure to wash sediment out of the way of the bit. In a similar manner, a center bit, which fills the opening in the bit face, can replace the core barrel if drilling ahead in hard sediments without coring is necessary.

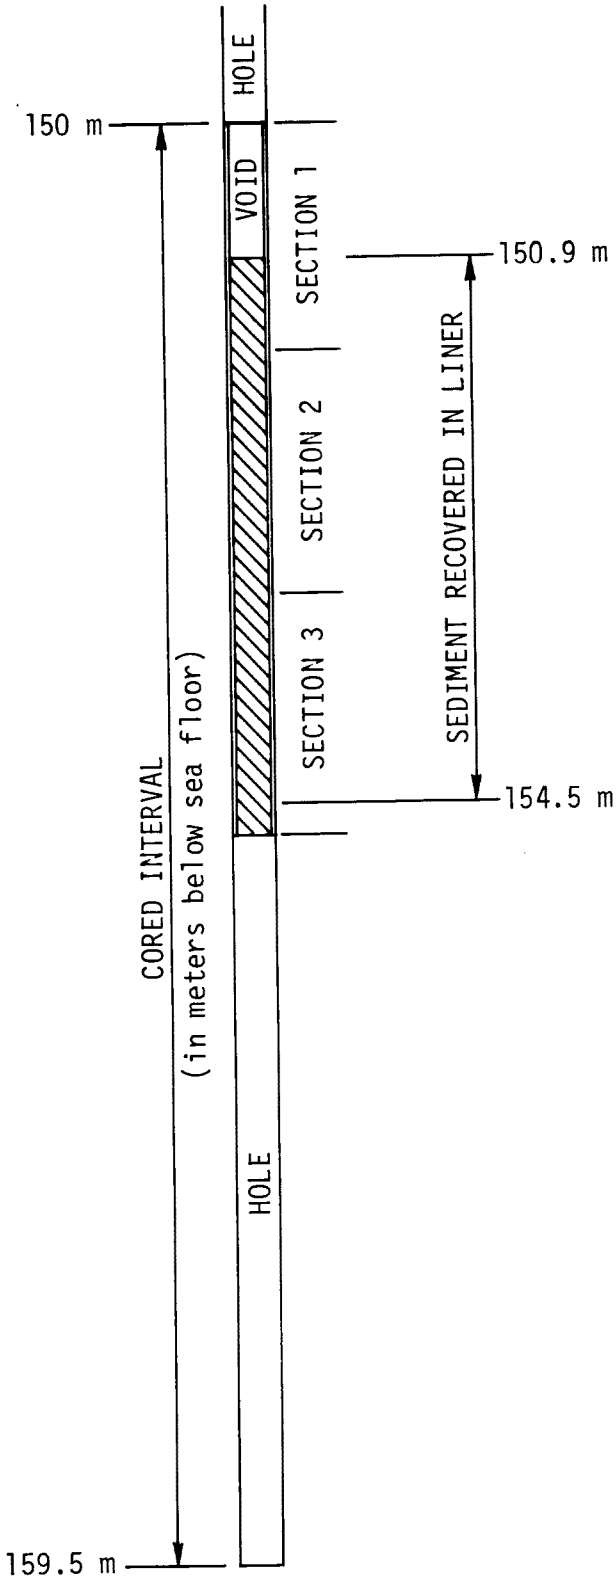
When a core is brought aboard the GLOMAR CHALLENGER it is labeled and the plastic liner and core cut into 1.5-meter sections. A full, 9-meter core would thus consist of six sections, numbered from the top down, 1 to 6. (The discrepancy between the 9-meter core and 9.5-meter cored interval is discussed below.) Generally, something less than 9 meters is recovered. In this case, the sections are still numbered starting with one at the top, but the number of sections is the number of 1.5-meter intervals needed to accomodate the length of core recovered; this is illustrated below:



Thus, as shown, recovery of 3.6 meters of sediment would result in a core with 3 sections, with a void of 0.9 meters at the top of the first section. By convention, and for convenience in routine data handling at the Deep Sea Drilling Project, if a core contains a length of material less than the length of the cored interval, the

recovered material is placed in the top of the cored interval, with the top of Section 1, rather than the top of the sediment, equal to the top of the cored interval. This is shown below for the core in the above example. Thus, the depth below the sea floor of the top of the sediment of this hypothetical core would lie at 150.9 meters (not 150.0 m) and the bottom at 154.5 meters.

It was noted above that a discrepancy exists between the usual coring interval of 9.5 meters and the 9-meter length of core recovered. The core liners used are actually 9.28 meters in length, and the core catcher accounts for another 0.2 meters. In cases where the core liner is recovered full to the top, the core is still cut into six 1.5-meter sections,



measured from the bottom of the liner, and the extra 0.28-meter section at the top is designated Section 0, or the "Zero Section". On Leg 43 every attempt was made to split and describe all zero sections. In the case of cores with zero sections, depth below sea floor is calculated by placing the top of Section 0 at the top of the cored interval.

In the core laboratory on the GLOMAR CHALLENGER, after routine processing, the 1.5-meter sections of sediment core and liner are split in half lengthwise. One half is designated the "archive" half, which is described by the shipboard geologists, and photographed; and the other is the "working" half, which is sampled by the shipboard sedimentologists and paleontologists for further shipboard and shorebased analysis.

Samples taken from core sections are designated by the interval in centimeters from the top of the core section from which the sample was extracted; the sample size, in cc, is also given. Thus, a full sample designation would consist of the following information:

Leg (Optional)
Site (Hole, if other than first hole)
Core Number
Section Number
Interval in centimeters from top of section

Site 382-1-3, 122-124 cm (10cc) designates a 10cc sample taken from Section 2 of Core 1 from the second hole drilled at Site 382. The depth below the sea floor for this sample would then be the depth to the top of the cored interval (46 meters in the example above) plus 3 meters for Sections 1 and 2, plus 122 cm (depth below the top of Section 3), or 50.2 meters. Note, however, that subsequent

sample requests should refer to a specific interval within a core section (in centimeters) rather than depth in meters below the sea floor.

Core Disturbance

Unconsolidated sediments are often quite disturbed by the rotary drilling/coring technique, and there is a complete gradation of disturbance style with increasing sediment induration. An assesment of degree and style of drilling deformation is made on board ship for all cored material, and shown graphically on the core description sheets. The following symbols are used:

---- Slightly deformed; bedding contacts slight bent.

__ __ Moderately deformed; bedding contacts have undergone extreme bowing.

≀ Highly deformed; bedding completely disturbed, often showing symmetrical diapir-like structures.

o o o Soupy, or drilling breccia; water-saturated intervals that have lost all aspects of original bedding and sediment cohesiveness.

Consolidated sediments and rocks seldom show much internal deformation, but are usually broken by drilling into cylindrical pieces of varying length. There is frequently no indication if adjacent pieces in the core liner are actually contiguous or if intervening sediment has been lost during drilling. The symbol (-o-o-o-) was used for cylindrical pieces of core separated by intervals of drilling breccia or injected (remolded) softer sediment.

Smear Slides

The lithologic classification of sediments is based on visual

estimates of texture and composition in smear slides made on board ship. These estimates are of areal abundances on the slide and may differ somewhat from the more accurate laboratory analyses of grain size, carbonate content, and mineralogy. Expierience has shown that distinctive minor components can be accurately estimated (±1 or 2%), but that an accuracy of ±10% for major constituents is rarely attained. Carbonate content is especially difficult to estimate in smear slides, as is the amount of clay present. Smear slide analyses at selected levels as well as averaged analyses for intervals of uniform lithology are given on the core description sheets. For carbonate content, reference should be made to shipboard carbonate bomb analyses and shore-based analyses (also shown).

Carbonate Data

During Leg 43, extensive use was made of the carbonate bomb device as an aid in sediment classification. This device is basically a cylindrical vessel with pressure gauge in which a sediment sample of known weight is reacted with acid. The pressure of CO_2 generated is measured and converted to percent carbonate. Accuracy to within ±5% total carbonate has been quoted for the device. Shipboard carbonate bomb data are listed in a separate column on the core description sheet.

Samples were taken from DSDP shore-base carbon-carbonate analysis using the Leco 70-second Analyser. These are also listed on the core description sheet and are distinguished from carbonate bomb values by italic type. Organic carbon content values obtained in the

15

Leco analyses are given in tabular form following core description sheets for each site.

X-ray Mineralogical Analyses

X-ray mineralogical analyses of Leg 43 sediments were provided by P. Rothe of the Leg 43 staff. These data are presented in tabular form following the core description sheets of each site. The percentages of constituent minerals are summed to 100% and are normalized to percent carbonate as determined by the bomb technique. The clay-mineral composition of the <2μm fraction is also given. At the time of this compilation, sediment names are based on the shipboard description of smear slides and have not been changed to resolve any discrepancies with the X-ray data.

Sediment Induration

The determination of induration is highly subjective, but field geologists have successfully made similar distinctions for many years. The criteria of Moberly and Heath (1971) are used for calcareous deposits; subjective estimate or behavior in core cutting is used for others.

a). Calcareous sediments

Soft: Oozes have little strength and are readily deformed under the finer or the broad blade of a spatula.

Firm: Chalks are partly indurated oozes; they are friable limestones that are readily deformed under the fingernail or the edge of a spatula blade.

Hard:Cemented rocks are termed limestones.

b). The following criteria are used for other sediments:

If the material is soft enough that the core can be split with a wire cutter, the sediment name only is used (e.g. silty clay; sand).

If the core must be cut on the band saw or diamond saw, the suffix 'stone' is used (e.g. silty claystone; sandstone).

Sediment Classification

The sediment classification scheme used on Leg 43 is basically that devised by the JOIDES Panel on Sedimentary Petrology and Physical Properties and adopted for use by the JOIDES Planning Committee in March, 1974, with minor modifications. The classification is outlined below.

I. General rules for class limits and order of components in a sediment name.

A. Sediment assumes the names of those components present only in quantities greater than 15%.

B. Where more than one component is present, the component in greatest abundance is listed farthest to the right, and other components are listed progressively to the left in order of decreasing abundance.

C. The class limits are based on percentage intervals given below for various sediment types.

II. Pelagic Clay

>10% authigenic components
<30% siliceous microfossils
<30% $CaCO_3$
<30% terrigenous components

III. Pelagic Siliceous BIogenic Sediments

>30% siliceous microfossils
<30% $CaCO_3$
<30% terrigenous components (mud)

17

Radiolaria dominant: radiolarian ooze (or radiolarite)
Diatoms dominant: diatom ooze (or diatomite)
Sponge spicules dominant: sponge spicule ooze (or spiculite)
Where uncertain: siliceous (biogenic) ooze (or chert, porcellanite)
When containing 10-30% $CaCO_3$: modified by nannofossil-----, foraminiferal-----,calcareous-----, nannofossil-foraminiferal-----, or foraminiferal-nannofossil-----, depending upon kind and quantity of $CaCO_3$ component.

IV. Transitional Biogenic Siliceous Sediments

10-70% siliceous microfossils
30-90% terrigenous components (mud)
<30% $CaCO_3$

If diatoms < mud: diatomaceous mud (stone)
If diatoms > mud: muddy diatom ooze (muddy diatomite)
If $CaCO_3$ 10-30%: appropriate qualifier is used (See III).

V. Pelagic Biogenic Calcareous Sediments

>30% $CaCO_3$
<30% terrigenous components
<30% siliceous microfossils

Principal components are nannofossils and foraminifera; qualifiers are used as follows:

Foram %	Name
<10	nannofossil ooze (chalk, limestone)
10-25	foraminiferal-nannofossil ooze
25-50	nannofossil-foraminiferal ooze
>50	foraminiferal ooze

Calcareous sediment containing 10-30% siliceous fossils carry the qualifier radiolarian, diatomaceous or siliceous depending upon the identification.

VI. Transitional Biogenic Calcareous Sediments

>30% $CaCO_3$
>30% terrigenous components
<30% siliceous microfossils

If $CaCO_3$ 30-60%: marly is used as a qualifier:

soft: marly calcareous (or nannofossil, etc.) ooze
firm: marly chalk (or marly nannofossil chalk, etc.)
hard: marly limestone (or marly nannofossil limestone, etc.)

If $CaCO_3$ >60%:

soft: calcareous (or nannofossil, etc.) ooze
firm: chalk (or nannofossil chalk, etc.)
hard: limestone (or nannofossil limestone, etc.)

NOTE: Sediments containing 10-30% $CaCO_3$ fall in other classes where they are denoted with the adjective "calcareous", "nannofossil", etc.

VII. Terrigenous Sediments

>30% terrigenous components
<30% $CaCO_3$
<10% siliceous microfossils
<10% authigenic components

Sediments in this category are subdivided into textural groups on the basis of the relative proportions of three grain-size components, i.e. sand, silt and clay. Sediments coarser than sand-size are treated as "Special Rock Types." The size limits are those defined by Wentworth (1922). The textural classification is according to the triangular diagram of Shepard (1954) (Figure). The suffix "-stone" is used to indicate hard or consolidated equivalents of the unconsolidated sediments.

If $CaCO_3$ is 10-30%: calcareous, nannofossil, etc. is used as a qualifier.

Other qualifiers (e.g. feldspathic, glauconitic, etc.) are used for components >10%.

VIII. Volcanogenic Sediments

a). Pyroclastic rocks are described according to the textural and compositional scheme of Wentworth and Williams (1932). The textural groups are:

Volcanic breccia >32 mm
Volcanic lapilli <32 mm
Volcanic ash (tuff, if indurated) <4 mm

Compositionally, these pyroclastic rocks are described as vitric (glass), crystal or lithic.

b). Clastic sediments of volcanic provenance are described in the same fashion as the terrigenous sediments, noting the dominant composition of the volcanic grains where possible.

IX. Special Rock Types

A. Volcanogenic sediments cored at Sites 382 and 385 include units with clastic volcanic components >32 mm in size which appear to have been displaced to deep water by gravitational processes and which may include pyroclastic debris. These rocks are referred to as "volcaniclastic breccias."

B. Limestones cored at Site 384 contain shallow-water reefal debris with a variety of calcite cement. These bioclastic limestones are classified according to the format of Folk (1962, 1968).

Biostratigraphy

At the time of this compilation biostratigraphic studies of Leg 43 material are still in progress. Revisions in nannofossil ages to date have been incorporated. A radiolarian specialist was not on board CHALLENGER during Leg 43; radiolarian zonal assignments should therefore by regarded as tentative. Major changes in the position of principal boundaries, however, are unlikely.

The Cenozoic planktonic foraminifer zonation used follows the letter/number scheme of Blow (1969). Cretaceous foraminifer zones follows the definitions of Cita and Gartner (1971) and van Hinte (1972). The nannofossil zonation is a composite one based on those of Martini (1971), Bukry (1975), and Gartner (1974). The letter/number designations of Martini are used with subzones distinguished by lower-case letters that follow the zone number.

sample-distribution policy

Distribution of Deep Sea Drilling samples will be undertaken in order to (1) provide supplementary data for inclusion in the appropriate Initial Report to support *Glomar Challenger* scientists in achieving the scientific objectives of their particular cruise, (2) provide individual investigators with material to conduct detailed studies beyond the scope of the Initial Reports, and (3) provide reference material for up to five reference centers where paleontologic materials are or will be available for reference/comparison purposes.

The National Science Foundation has established a Sample Distribution Panel to advise on distribution of core material. This panel is chosen in accordance with usual Foundation practices, in a manner that will assure advice in the various disciplines leading to a complete and adequate study of the core and related materials. Funding for the proposed research is handled separately by the investigator, not through the Deep Sea Drilling Project.

1. Distribution of Samples for Contributions to Initial Reports

Any investigator who wishes to contribute a paper to a given volume of the Initial Reports may write to the Chief Scientist, Deep Sea Drilling Project, Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, requesting samples from a forthcoming cruise. The request should include the nature of the study, and type, size, number of samples, particular sampling techniques or equipment that might be required, and an estimate of the time required to complete the study. The requests will be reviewed by shipboard scientists, and, if they are deemed suitable and pertinent to the objectives of the leg, and shipboard workload permits, the requested samples will be taken during the cruise (provided, of course, material suitable to the investigation is obtained during the drilling). In case of multiple requests to perform the same investigation, selection of investigator will be made by the shipboard scientific party. Proposals should be of a scope appropriate to complete the sampling and study in time for publication in the Initial Reports. Studies deemed acceptable will be referred to the DSDP Chief Scientist who will authorize distribution of the samples. The Deep Sea Drilling Project and cruise Chief Scientists will strive to ensure that there is a reasonable degree of continuity in the investigations among the various cruises, that the studies are pertinent to goals of the cruise, and that they are consistent with the publication policy for the Initial Reports. Subject to these same provisions, the shipboard scientific party may elect to have special studies of selected core samples of its recently completed cruise made by other investigators.

Investigations not completed in time for inclusion in the Initial Report may not be published in other journals until publication of the Initial Report for which it was intended though it is expected that they will normally be published as an appendix in a later Initial Report volume.

2. Distribution of Samples for Publication Other Than in Initial Reports

(A) Researchers intending to request samples for studies beyond the scope of the Initial Reports should first obtain a sample request form from the Curator, Deep Sea Drilling Project, Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California 92093. Requests should specify the quantities and intervals of the core required, a statement of the proposed research, the possibility of returning residue to the Curator, the estimated time required to complete and publish the results, and the availability or need of funding and availability of equipment and space foreseen for the research.

In order to ensure that requests for highly desirable but limited samples can all be considered, approval of requests and distribution of samples will not be made prior to 12 months after date of completion of the cruise that collected the cores. Prior to the publication of an Initial Report, requests for samples from a cruise can be based on the Initial Core Descriptions (ICDs). Copies of the ICDs will be kept on open file at Scripps Institution of Oceanography and other designated institutions. The only exceptions to this policy will be for specific instances involving requests for sands with ephemeral properties.

Requests for samples from researchers in industrial laboratories will be handled in the same manner as those from academic organizations, and there will be the same obligation to publish results promptly. Requests from foreign scientists or organizations will also be considered and handled in a like manner.

(B) The Deep Sea Drilling Project's Curator has the responsibility for distributing samples, controlling quality of samples, and preserving core material. He also has the responsibility for maintaining a record of requests for samples that have been processed and filled indicating the investigator and subjects to be studied. This record will be available to investigators.

The distribution of samples will be made directly from the two repositories at Lamont-Doherty Geological Observatory and Scripps Institution of Oceanography by the Curator or his designated representative.

(C) (i) Samples up to 50 cc/m of core length can be automatically distributed by the Curator, Deep Sea Drilling Project, or his authorized representative to any qualified investigator who requests them. The Curator will refrain from making automatic distribution of any parts of the cores which appear to be in particularly high demand or limited supply, and any requests for these parts of the cores will be referred to the Sample Distribution Panel for review. Requests for samples from thin layers or important stratigraphic boundaries will also generally require Panel review. (ii) All requests for samples in excess of (C) (i) above will be referred to the Sample Distribution Panel. (iii) If, in the opinion of scientific investigators, certain properties they wish to study may deteriorate prior to the normal availability of the Samples, such investigators may request that the normal waiting period not apply. All such requests must be approved by the Sample Distribution Panel.

(D) Samples will not be provided prior to assurance that funding for sample studies either exists or is not needed. However, neither formal approval of sample requests nor distribution of samples will be made until the appropriate time (Item 1). If a sample request is dependent, either wholly or in part, on proposed funding, the Curator will provide to the organization to whom the funding proposal has been submitted any information on the availability (or potential availability) of samples that it may request.

(E) Investigators receiving samples are responsible for: (i) Promptly publishing significant results; (ii) Acknowledging, in publications, that samples were supplied through the assistance of the National Science Foundation; (iii) Submitting five (5) copies of all reprints of published results to the Curator, Deep Sea Drilling Project, Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California 92093; (iv) Notifying the Curator of any work done on the samples that is additional to that stated in the original request for samples; (v) Returning, in good condition, the remainders of samples after termination of research, if requested by the Curator.

(F) Cores will be made available at repositories for investigators to examine and specify exact samples in such instances as this may be necessary for the scientific purposes of the sampling, subject to the limitations of (C) (i) (ii) (iii) and (E) above, and with the specific permission of the Curator or his delegate.

(G) Cores of igneous and metamorphic rocks will also remain at the repositories where they will be available for observation and description and where selected samples may be taken for thin-section preparation and other work.

(H) The Deep Sea Drilling Project routinely processes by computer most of the quantitative data presented in the Initial Reports. Space limitations in the Initial Reports preclude the detailed presentation of all such data. However, copies of the computer readout are available for those who wish the data for further analysis or as an aid in selecting samples.

3. Reference Centers

As a separate and special category, samples may be distributed for the purpose of establishing up to five reference centers where paleontologic materials are available for reference/comparison purposes. Such reference centers shall be approved by the National Science Foundation before sample distribution. Samples will be distributed to the institution managing the reference center. Therefore assurance of adequate long-term curatorial management is a requisite of the establishment of any such reference center.

4. Other Records

Magnetics, seismic reflection, and bathymetric data collected underway by *Glomar Challenger* will also be available for distribution 12 months after completion of the cruise.

Requests for these data may be made to Director, Science Services, Deep Sea Drilling Project, Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California 92093.

A charge may be made to recover the expenses of responding to individual requests. Estimated charges can be furnished before the request is processed, if required.

This policy has the approval of the National Science Foundation and is designed to help ensure that the greatest possible scientific benefit is gained from the materials obtained and that samples will be made widely available to interested geologists.

DEEP SEA DRILLING PROJECT

LEG 43 SITE 382

SITE SUMMARY SHEET

POSITION: Latitude: 34°25.05'N Longitude: 56°32.25'W

Water depth (sea level): 5526 corrected meters, echo sounding

Bottom felt at: 5537 meters, drill pipe Penetration: 520.5 meters

Number of holes: 1 Number of cores: 25

Total length of cored section: 232.2 meters

Total core recovered: 163.4 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 520.5 meters Nature: Volcaniclastic breccia

Age: Coniacian-Santonian or older

BASEMENT*:

Depth subbottom: 520.5 meters Nature: Volcaniclastic breccia

Velocity range: 3.4-4.2 km/s

PRINCIPAL RESULTS:

The sedimentary section above the buried eastern flank of Nashville Seamount was sampled down to subbottom depth of 520.5 meters. The hole bottomed in coarse volcaniclastic breccia attributed to volcanism on Nashville Seamount. Slow progress of penetrating the breccia and consideration of time restrictions led us to abandon the hole at this level.

The sedimentary sequence at Site 382 can be summarized as follows, (with average sedimentation rates in parentheses): 0 to 232 meters subbottom depth, Quaternary clays, silty clays, and silts (120 m/m.y.);

---

*Basement here is the top of seamount flank volcanics, and not original oceanic basement which lies an indeterminate distance further down.

25

232-352 meters, mid-Pliocene to lower Miocene hemipelagic clays (8 m/m.y.); 352-385 meters, Maestrichtian to Campanian varicolored (volcanogenic) silty clays (2 m/m.y.); 385-520.5 meters, lower Campanian volcanogenic clay, silty clay, marly limestone and volcaniclastic breccia overlying Coniacian-Santonian volcanogenic claystones and sandstones over breccia (12 m/m.y.). A hiatus of some 40 m.y. occurs between the lower Miocene and the Maestrichtian. The rapidly deposited Quaternary silty clays represent a succession of distal turbidites and show that the Sohm abyssal plain did not spread this far until the early Pleistocene. The 40 m.y. hiatus probably reflects some combination of current erosion and local slumping off the seamount's flanks. Volcanic activity on Nashville Seamount was already in progress in the Coniacian-Santonian and continued to produce coarse volcaniclastic debris into the Campanian. This volcanism helps explain the relatively high sedimentation rate (12 m/m.y.) during this interval. High vesicularity of basaltic clasts indicates that the summit of Nashville Seamount was close to sea level, or even emergent, during the interval Coniacian-Santonian to Campanian. Finer-grained deposits and lower sedimentation rates during the Maestrichtian suggest a waning of volcanic activity, if in fact the material was not introduced from more distant sources. Numerous Campanian to lower Maestrichtian ash horizons encountered 450 km away at DSDP Site 10 may have been derived from Nashville Seamount.

Although the "original" basement was probably not reached, we estimated that about 10-15 m.y. elapsed between formation of basement and the lowermost breccia. Measured along the flow lines of plate motion, Site 382 lies exactly midway between anomaly J-6 and DSDP Site 10. The former is believed to date from 113-117 m.y. BP and the latter (lower to mid-Campanian) from 75-80 m.y. BP. If the late Cretaceous to Eocene sedimentation rate (2 m/m.y.) measured at Stie 9 also applies at Site 382, a minimum of 20-30 meters of sediment may be present between the lower breccia and original basement.

Core 2 is comprised of subequal amounts of quartzose silt and sand and quartzose silty clay.
Quartzose silt and sand (about 55% of Core 2) Three beds of dark gray and dark grayish brown quartzose silt and sand averaging about 80 cm in thickness occur in Core 2. A 120 cm thick bed of silt occurs at the top of the core. The lower 20 cm is coarser than the rest but the interval is too disturbed to tell if the grading is natural or produced by the drilling. A 50 cm thick graded bed is in sharp contact with underlying silty clay at 2-105 cm and overlying silty clay at 2-55 cm. Grading is from coarse to medium sand at the base containing pelecypod fragments to silt at the top. A silt layer at least 75 cm thick is in gradational contact with overlying silty clay at 3-75 cm and extends to the bottom of the core.
Smear Summary of 4 Slides of the Quartzose Silt and Sand

Core 1 is comprised of quartzose clay with interbeds of silty clay, silt, and sand.
Quartzose clay (60% of Core 1) The upper 4.1 m thick clay bed is dark grayish brown, very disturbed, with extremely rare black wood and/or coal fragments scattered throughout. The lower 1.25 m thick clay bed is dark gray to olive gray, very disturbed, with local stringers of silt scattered throughout. One 5 cm thick reddish brown clay bed occurs at 4-5-10 cm.

Quartzose silt and sand (10% of Core 1) Three coarser interbeds occur in Core 1. A 10 cm thick dark gray quartzose silty sand layer is in sharp contact with underlying silty clay and overlying clay in 3-120-130 cm. A 46 cm thick dark grayish brown graded bed of quartzose silt is in sharp contact with underlying silty clay at 4-118 cm. Grading is from sandy silt at the base to clayey silt at the upper gradational contact with silty clay. A 35 cm thick dark gray quartzose silty sand layer is in sharp contact with underlying clay and overlying silty clay in 6-9-44 cm. The middle portion of this layer is slightly coarser than the upper and lower portions. The general composition of these three layers is similar with the coarser portions enriched in quartz and the finer portions enriched in clay.

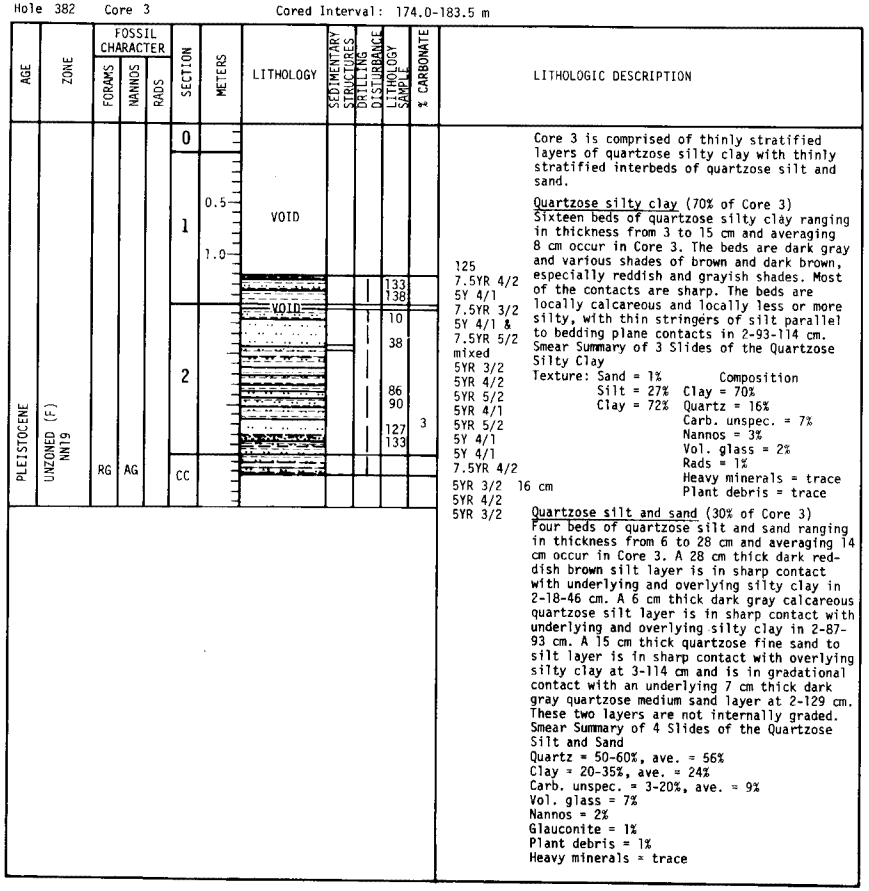
Hole 382 Core 3 Cored Interval: 174.0-183.5 m



LITHOLOGIC DESCRIPTION

Core 3 is comprised of thinly stratified layers of quartzose silty clay with thinly stratified interbeds of quartzose silt and sand.

Quartzose silty clay (70% of Core 3)
Sixteen beds of quartzose silty clay ranging in thickness from 3 to 15 cm and averaging 8 cm occur in Core 3. The beds are dark gray and various shades of brown and dark brown, especially reddish and grayish shades. Most of the contacts are sharp. The beds are locally calcareous and locally less or more silty, with thin stringers of silt parallel to bedding plane contacts in 2-93-114 cm.

Quartzose silt and sand (30% of Core 3)
Four beds of quartzose silt and sand ranging in thickness from 6 to 28 cm and averaging 14 cm occur in Core 3. A 28 cm thick dark reddish brown silt layer is in sharp contact with underlying and overlying silty clay in 2-18-46 cm. A 6 cm thick dark gray calcareous quartzose silt layer is in sharp contact with underlying and overlying silty clay in 2-87-93 cm. A 15 cm thick quartzose fine sand to silt layer is in sharp contact with overlying silty clay at 3-114 cm and is in gradational contact with an underlying 7 cm thick dark gray quartzose medium sand layer at 2-129 cm. These two layers are not internally graded.

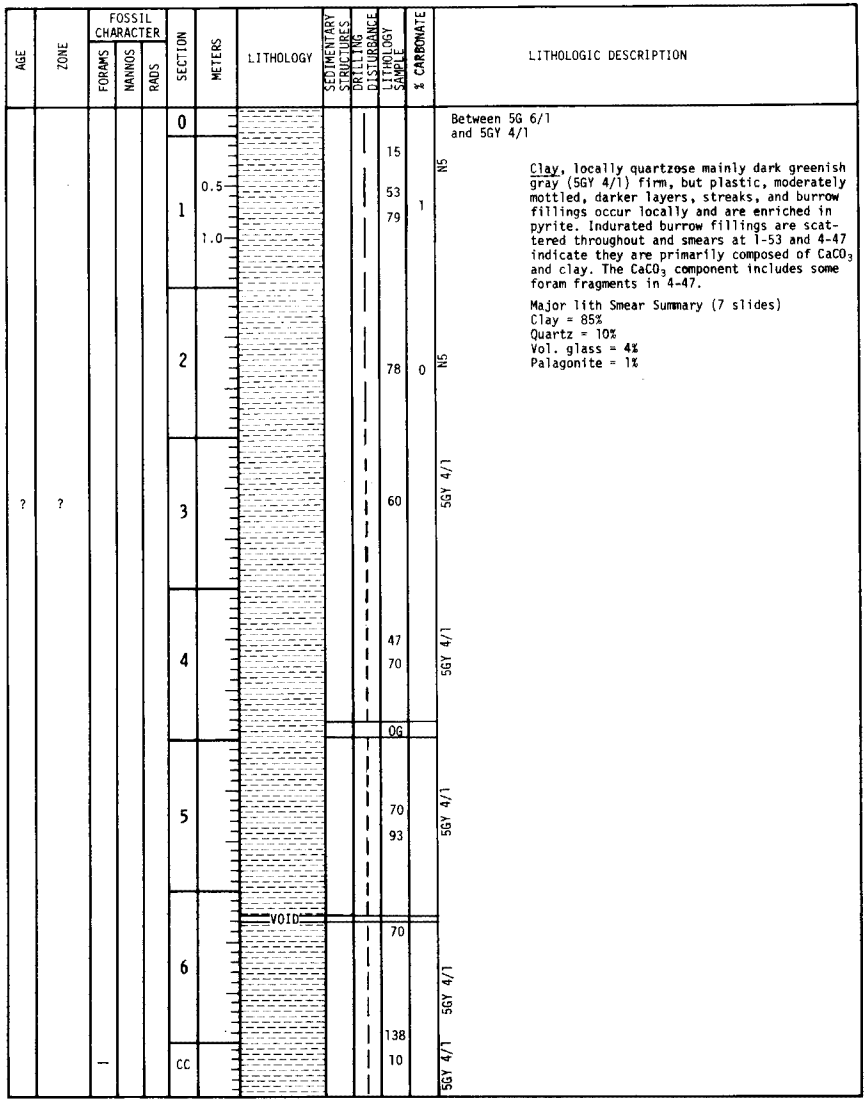
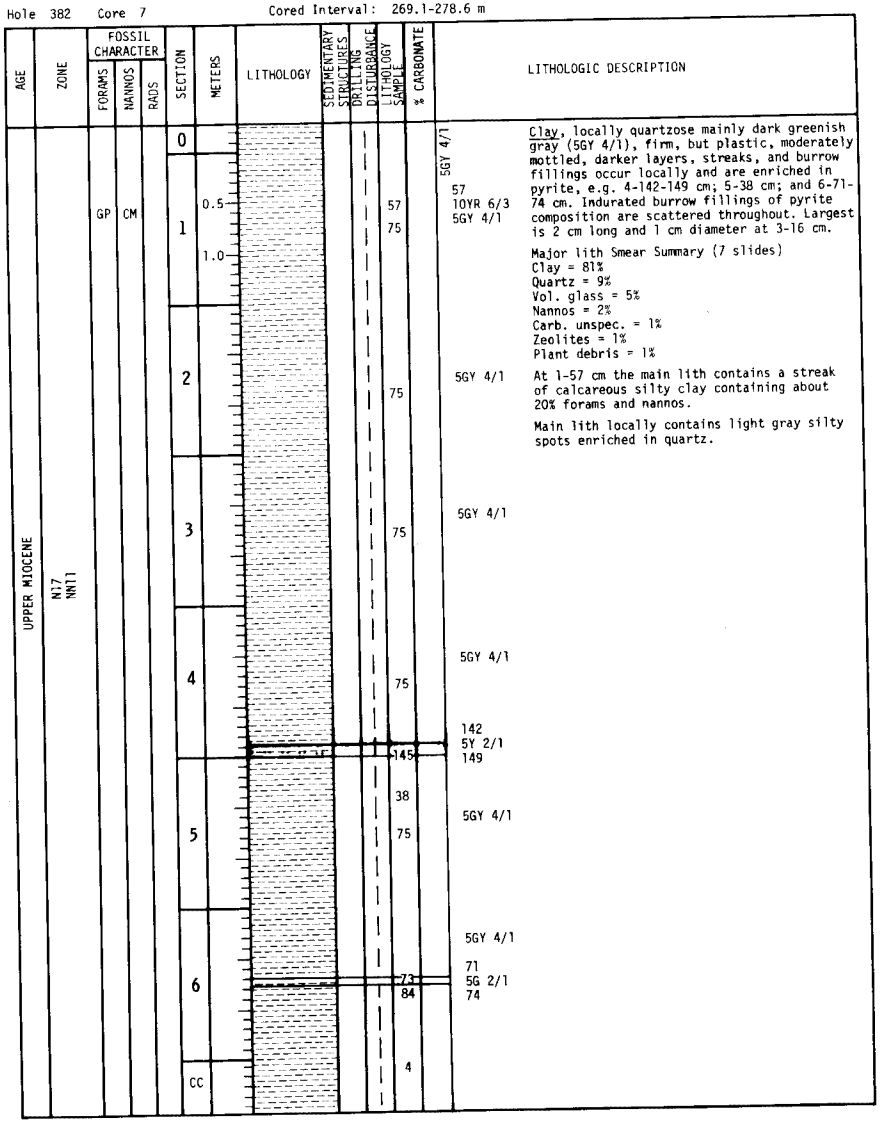
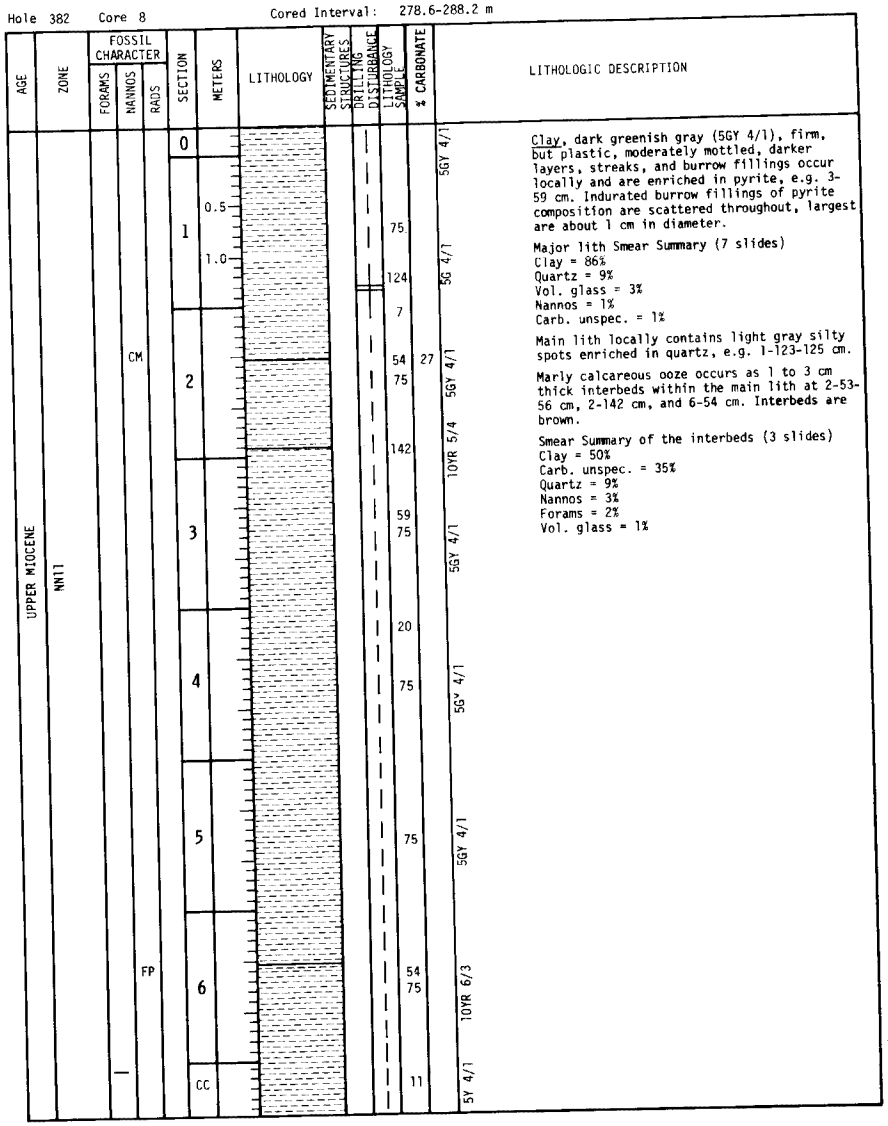
Hole 382 Core 6 Cored Interval: 250.1-259.6 m



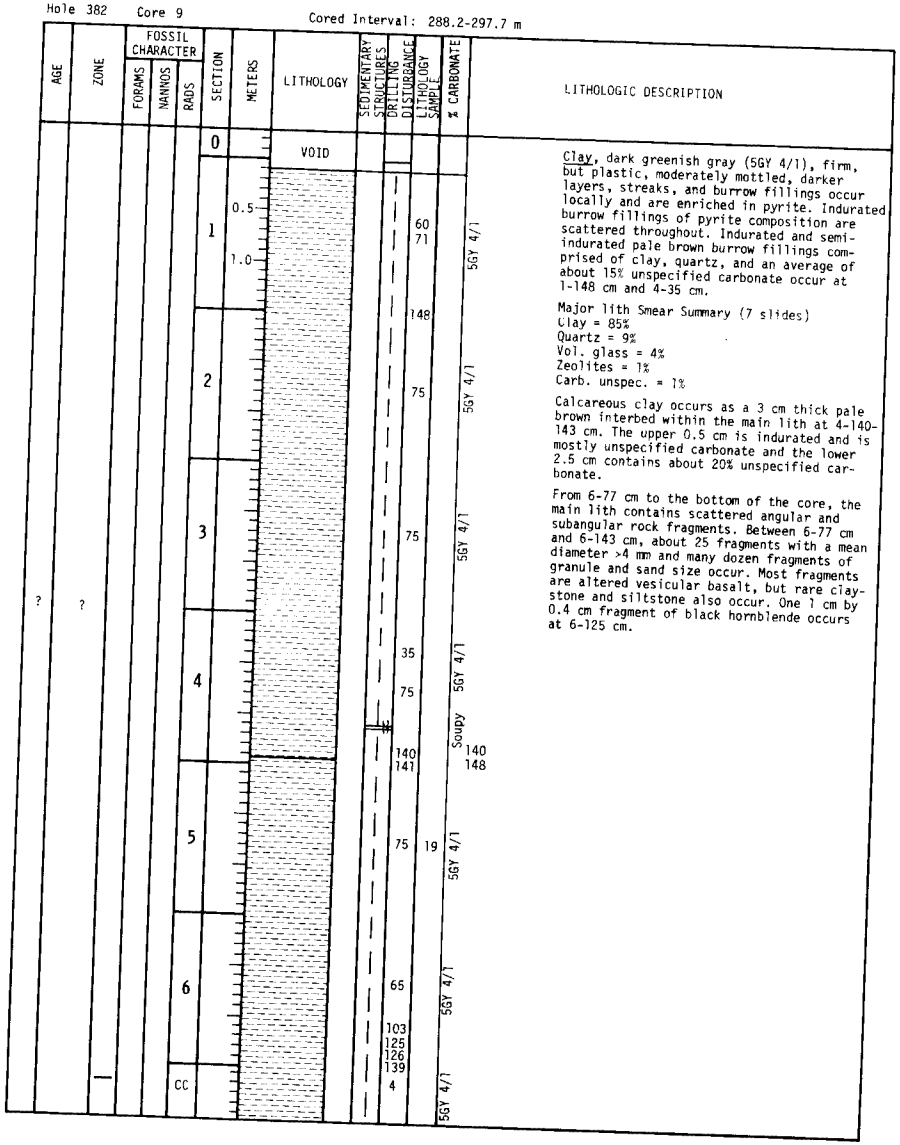
Hole 382 Core 7 Cored Interval: 269.1-278.6 m



Hole 382 Core 8 Cored Interval: 278.6-288.2 m



Hole 382 Core 9 Cored Interval: 288.2-297.7 m



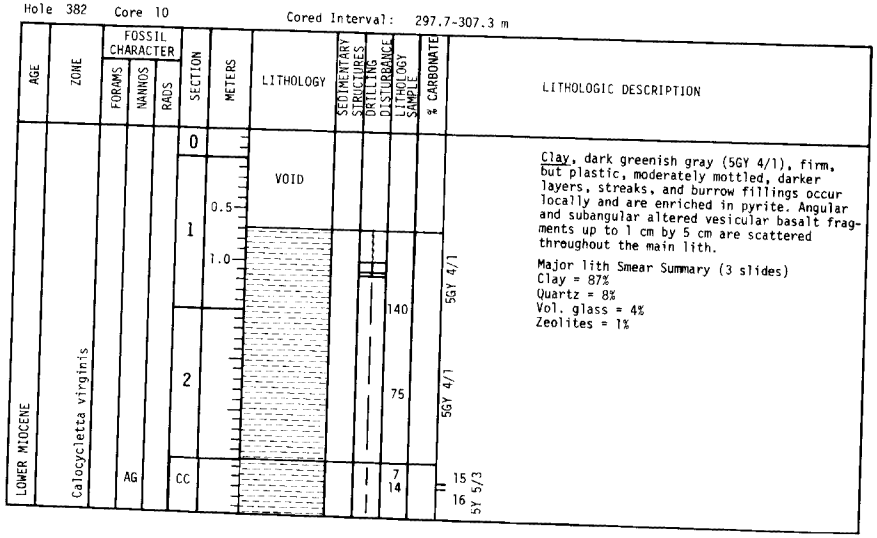
Clay, dark greenish gray (5GY 4/1), firm, but plastic, moderately mottled, darker layers, streaks, and burrow fillings occur locally and are enriched in pyrite. Indurated burrow fillings of pyrite composition are scattered throughout. Indurated and semi-indurated pale brown burrow fillings comprised of clay, quartz, and an average of about 15% unspecified carbonate occur at 1-148 cm and 4-35 cm.

Major lith Smear Summary (7 slides)
Clay = 85%
Quartz = 9%
Vol. glass = 4%
Zeolites = 1%
Carb. unspec. = 1%

Calcareous clay occurs as a 3 cm thick pale brown interbed within the main lith at 4-140-143 cm. The upper 0.5 cm is indurated and is mostly unspecified carbonate and the lower 2.5 cm contains about 20% unspecified carbonate.

From 6-77 cm to the bottom of the core, the main lith contains scattered angular and subangular rock fragments. Between 6-77 cm and 6-143 cm, about 25 fragments with a mean diameter >4 mm and many dozen fragments of granule and sand size occur. Most fragments are altered vesicular basalt, but rare claystone and siltstone also occur. One 1 cm by 0.4 cm fragment of black hornblende occurs at 6-125 cm.

Hole 382 Core 10 Cored Interval: 297.7-307.3 m



Clay, dark greenish gray (5GY 4/1), firm, but plastic, moderately mottled, darker layers, streaks, and burrow fillings occur locally and are enriched in pyrite. Angular and subangular altered vesicular basalt fragments up to 1 cm by 5 cm are scattered throughout the main lith.

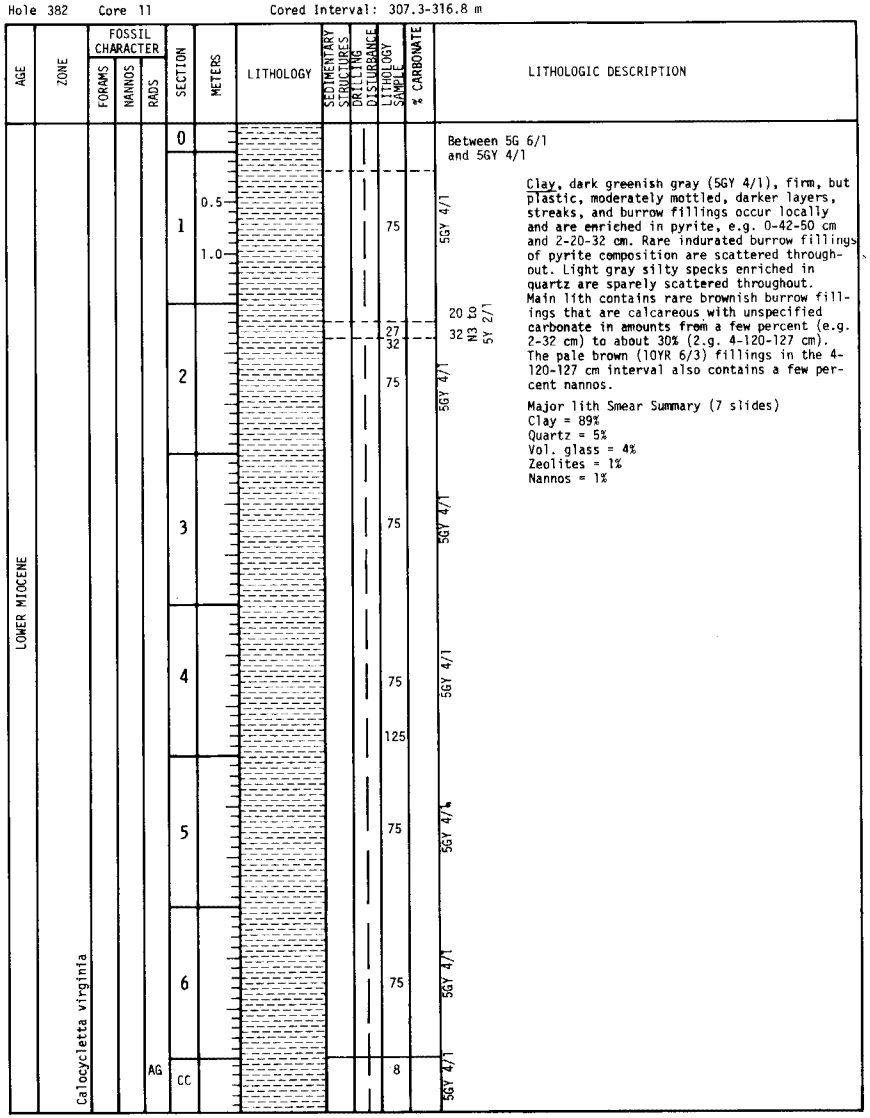
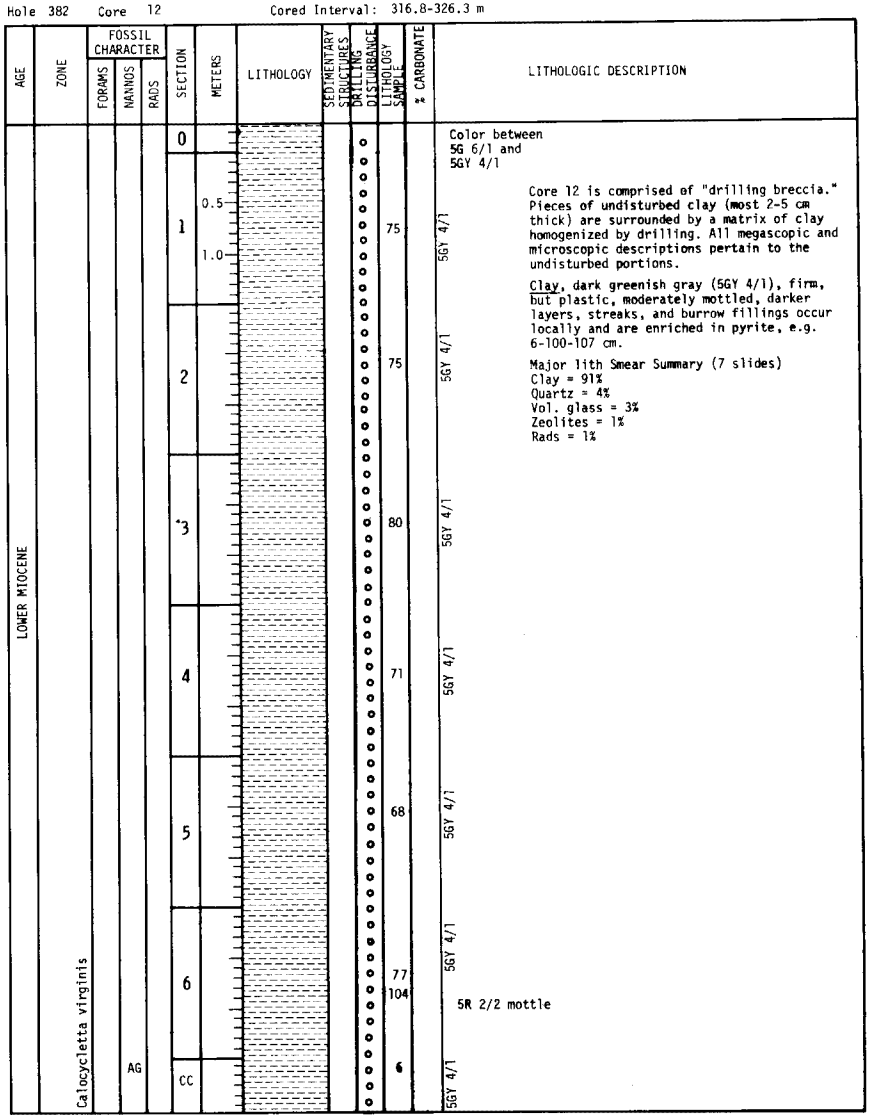
Zeolites = 1%

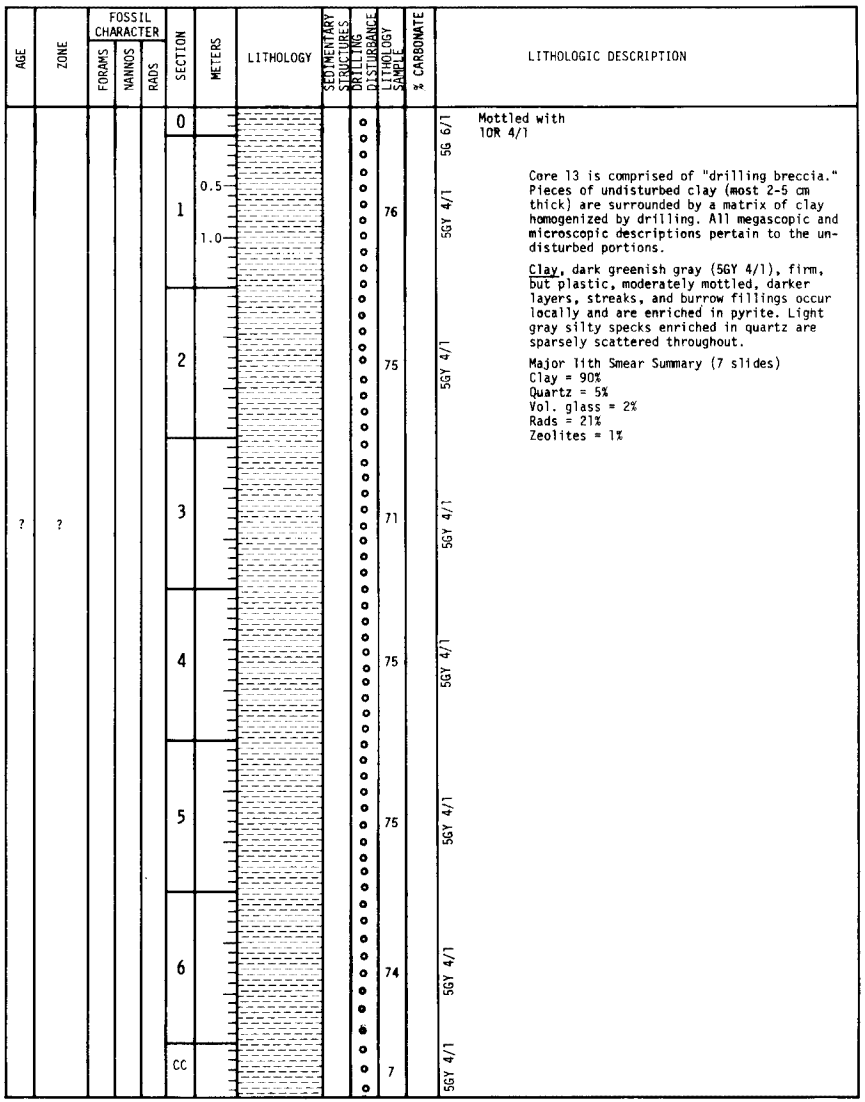
Hole 382 Core 11 Cored Interval: 307.3-316.8 m



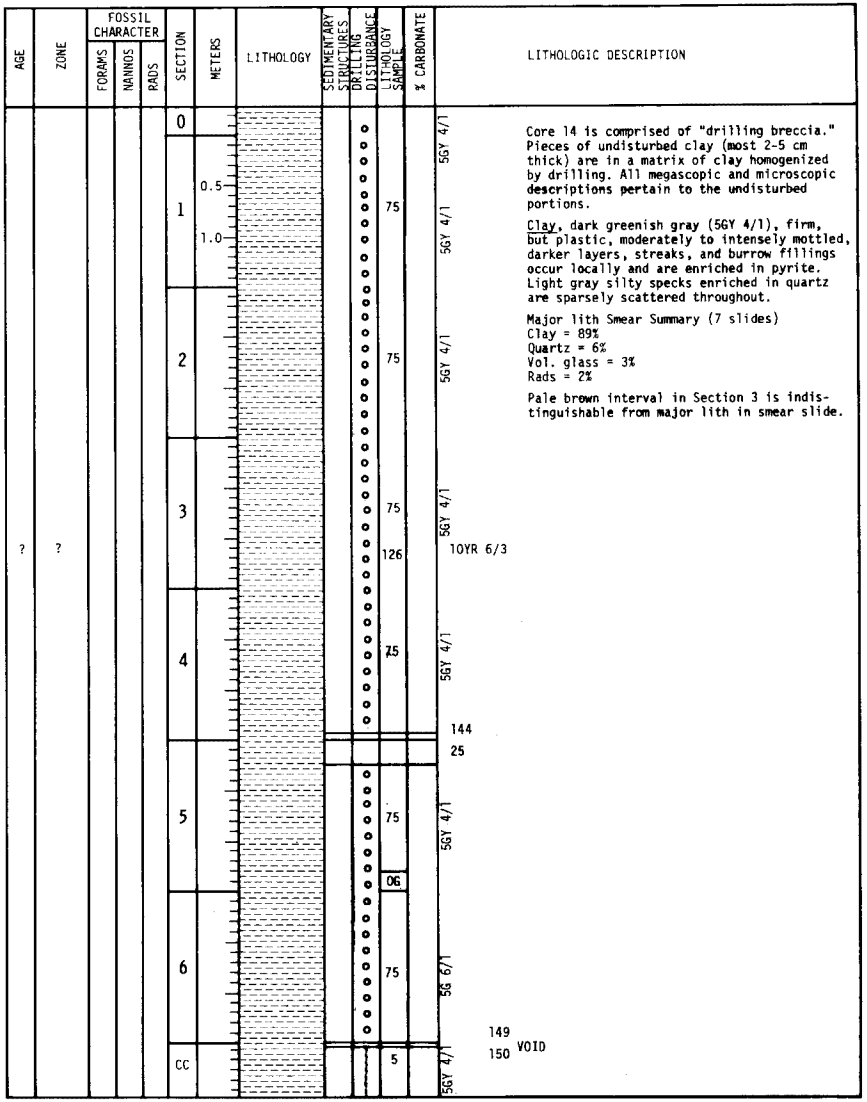
Hole 382 Core 12 Cored Interval: 316.8-326.3 m



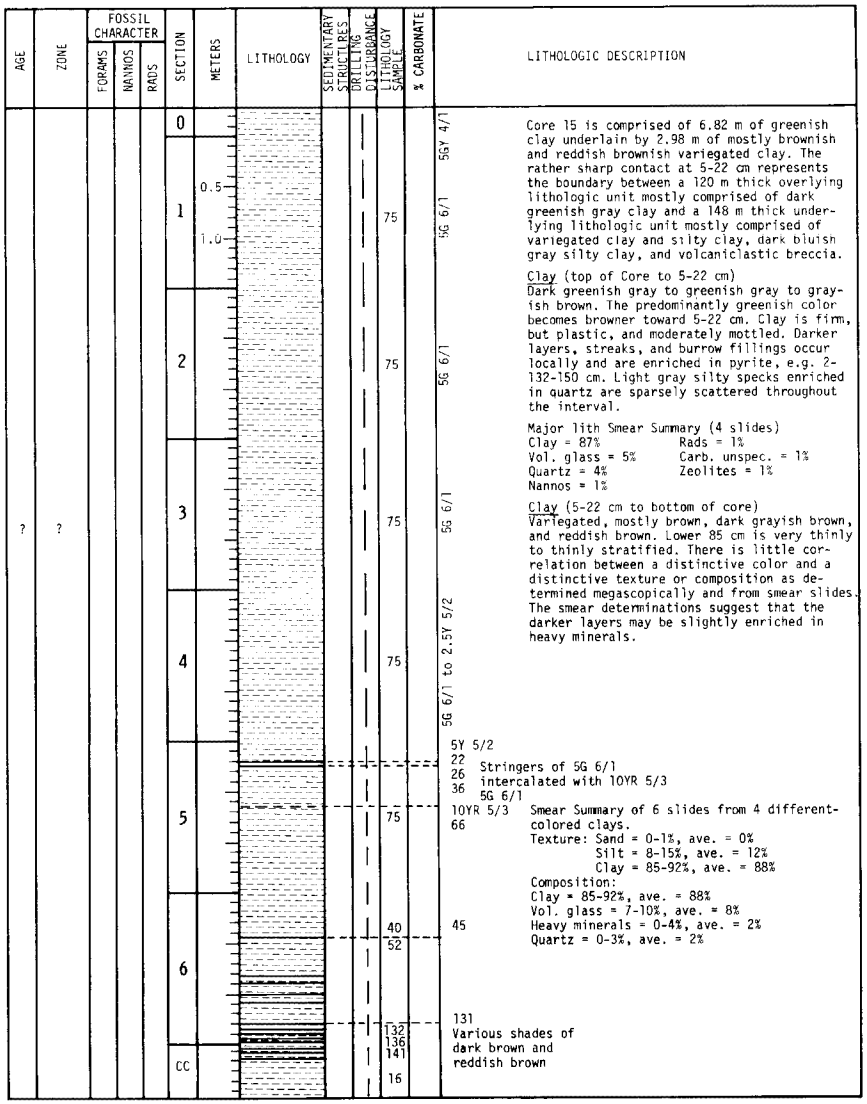
Hole 382 Core 13 Cored Interval: 326.3-335.8 m



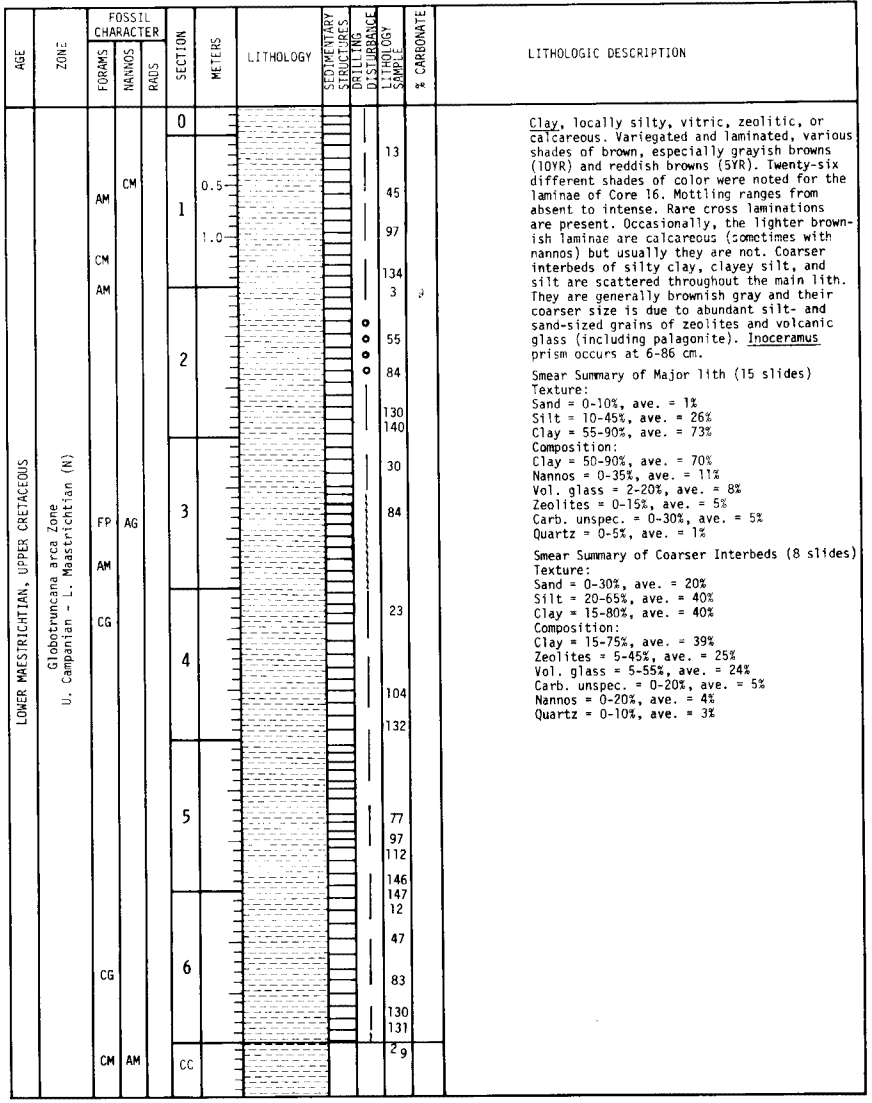
Hole 382 Core 14 Cored Interval: 335.8-345.3 m



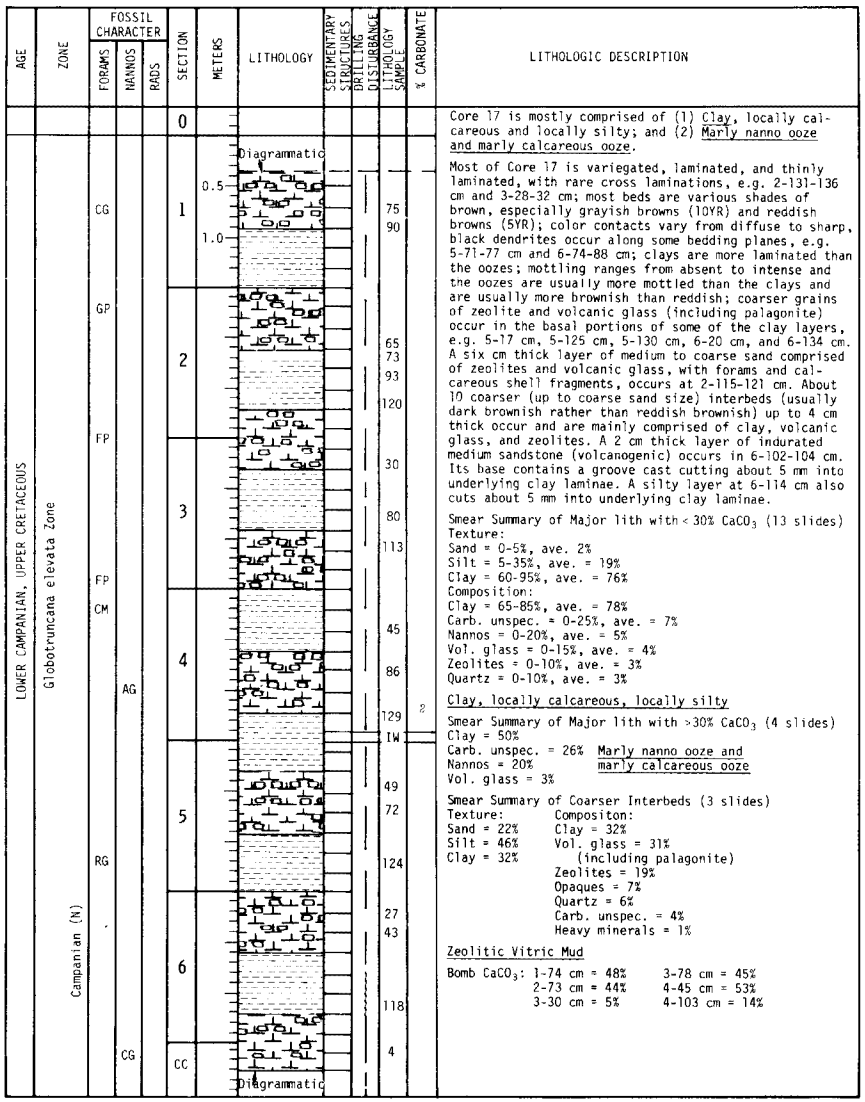
Hole 382 Core 15 Cored Interval: 345.3-354.8 m



Hole 382 Core 16 Cored Interval: 354.8-364.4 m



Hole 382 Core 17 Cored Interval: 364.4-373.8 m



Core 17 is mostly comprised of (1) Clay, locally calcareous and locally silty; and (2) Marly nanno ooze and marly calcareous ooze.

Most of Core 17 is variegated, laminated, and thinly laminated, with rare cross laminations, e.g. 2-131-136 cm and 3-28-32 cm; most beds are various shades of brown, especially grayish browns (10YR) and reddish browns (5YR); color contacts vary from diffuse to sharp, black dendrites occur along some bedding planes, e.g. 5-71-77 cm and 6-74-88 cm; clays are more laminated than the oozes; mottling ranges from absent to intense and the oozes are usually more mottled than the clays and are usually more brownish than reddish; coarser grains of zeolite and volcanic glass (including palagonite) occur in the basal portions of some of the clay layers, e.g. 5-17 cm, 5-125 cm, 5-130 cm, 6-20 cm, and 6-134 cm. A six cm thick layer of medium to coarse sand comprised of zeolites and volcanic glass, with forams and calcareous shell fragments, occurs at 2-115-121 cm. About 10 coarser (up to coarse sand size) interbeds (usually dark brownish rather than reddish brownish) up to 4 cm thick occur and are mainly comprised of clay, volcanic glass, and zeolites. A 2 cm thick layer of indurated medium sandstone (volcanogenic) occurs in 6-102-104 cm. Its base contains a groove cast cutting about 5 mm into underlying clay laminae. A silty layer at 6-114 cm also cuts about 5 mm into underlying clay laminae.

Siltstone and sandstone (indurated)
Generally darker-colored than the clays, mostly shades of dark grayish brown, dark brown, and dark reddish brown; occur as stringers and interbeds in this predominantly silty clay core, thickness ranges from about 1 mm to 3 cm; grain size ranges from silt to very coarse sand; some interbeds are crudely graded, e.g. 3-125-127 cm and 3-133-134 cm; a 4 cm thick pale brown interval in 2-64-68 cm grades from sand at the base to clay in the middle to silt at the top; a 1 cm thick ss layer at 1-140 cm contains two 5 mm diameter clay biebs; the stringers are generally in gradational contact with the clay, the 1 cm to 3 cm thick beds are generally in sharp contact with underlying and overlying clay. The siltstones and sandstones are mostly comprised of clay, zeolites, and volcanic glass (including palagonite).

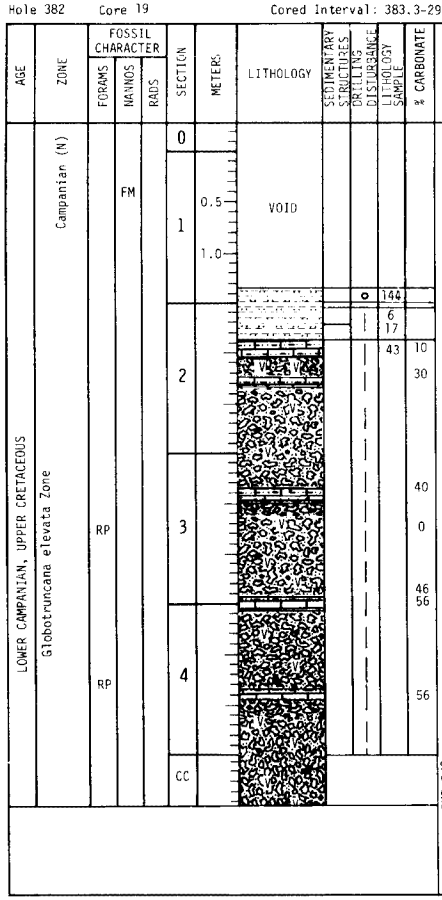
Hole 382 Core 19 Cored Interval: 383.3-293.8 m



Core 19 is mostly comprised of 4.22 m of volcaniclastic breccia interbedded with marly limestone, overlain by 53 cm of variegated calcareous silty clay.

Calcareous silty clay, variegated mostly shades of reddish brown (top of core to 2-38 cm) firm, but plastic, laminated, one cm thick interbed of coarse sand at 2-27 cm, unit is virtually identical to lith in Core 18.

Smear Summary of Calcareous Silty Clay (3 slides)

Texture:	Composition:	
Sand = 1%	Clay = 65%	Quartz = 3%
Silt = 34%	Carb. unspec. = 23%	Nannos = 2%
Clay = 65%	Vol. glass = 6%	Heavy minerals = 1%

Calcareous Cylindrichnus burrow fillings up to 1 mm diameter and 5 mm length occur at 2-18-20 cm.

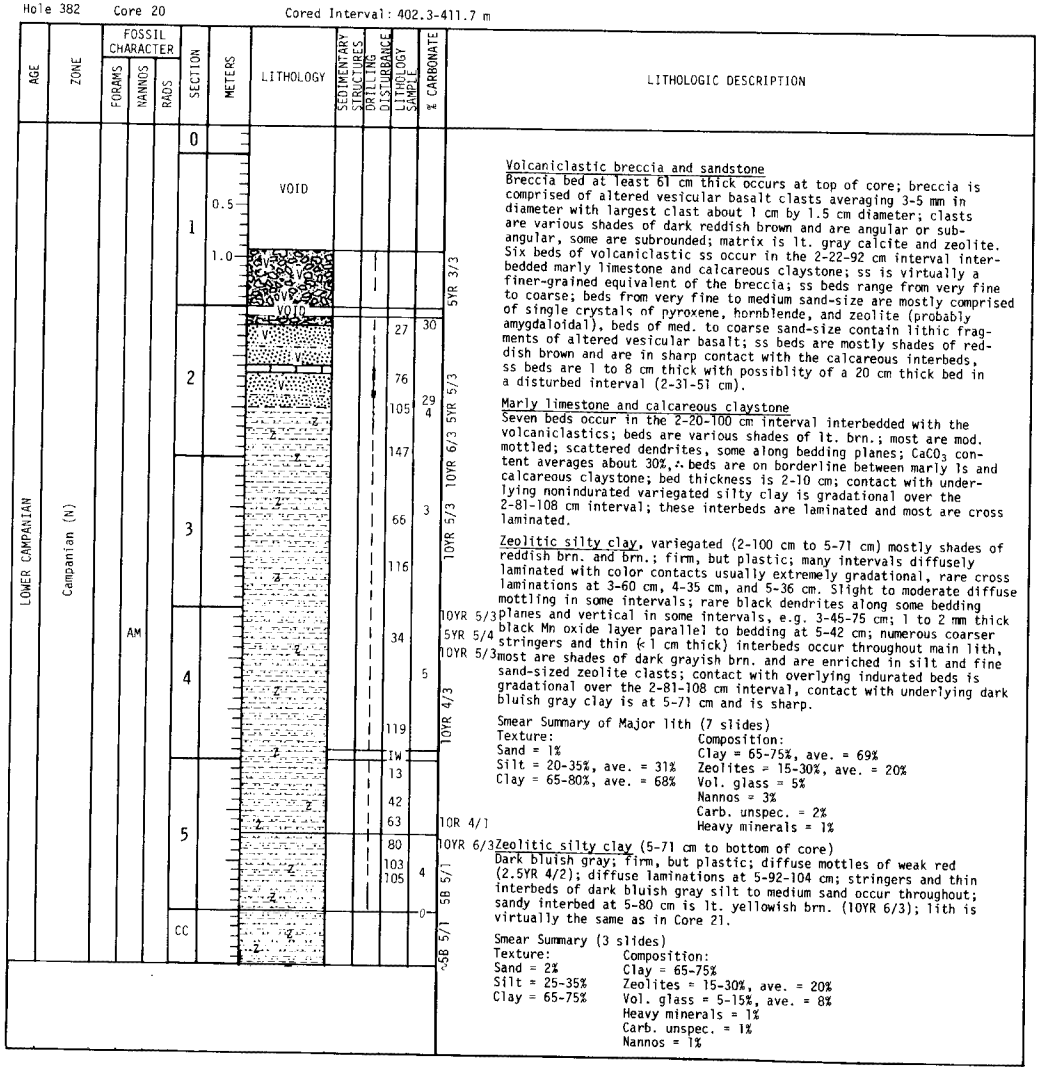
Volcaniclastic breccia

Seven beds and a few thin interbeds of volcaniclastic breccia occur from 2-54 cm to the bottom of the core catcher; beds range from 5 to 97 cm and average 50 cm in thickness; breccia is interbedded with marly ls and calcareous claystone; breccia is comprised of altered vesicular basalt clasts, most in the 2-5 mm diameter range with the max. clast size < 1 cm diameter in all but one bed; the two largest clasts occur in the core catcher and are 2 cm by 4 cm and 3 cm by 3 cm; in general, all the breccias are poorly sorted; clasts are mostly angular or subangular, some are subrounded; most clasts are various shades of reddish brown, less altered clasts are shades of dark gray; matrix is lt. gray zeolite and calcite and is volumetrically much less abundant than the clasts; most of the basal contacts with the interbeds are sharp, about half the upper contacts are sharp, half are gradational, dendrites occur along some of the sharp contacts; interbedded breccia and volcaniclastic ss at 2-128-134 cm are cross bedded; breccia at 3-41-46 cm appears to be reversely graded and the basal contact dips at about 10°; bed at 3-48-145 cm is crudely graded; bed at 4-9-85 cm is crudely graded with the 13-40 cm interval cross bedded with dips up to 20°; bed at 4-95-150 cm has much cross bedding with 5-10°dips.

Marly Limestone and Calcareous Claystone

Seven beds in the 2-38 cm to 4-95 cm interval are interbedded with the breccia; beds range from 2 to 11 cm and ave. 8 cm in thickness; beds are mostly comprised of unspecified carbonate and clay. Bomb results show most beds are marly ls (40-56% $CaCO_3$) but some are claystone; beds are slightly to intensely mottled, laminated, and cross laminated; all beds are shades of grayish brown except the 4-86-94 cm interval which is shades of reddish brown with the lower 5 cm laminated, the middle 2 cm cross laminated with an erosional basal contact, and the upper cm thinly laminated with an erosional basalt contact; black dendrites occur throughout and are concentrated on some bedding planes, vertical fracture containing dendrites extends from 4-89-100 cm, i.e. from ls into breccia; Inoceramus plate occurs at 3-38 cm.

Hole 382 Core 20 Cored Interval: 402.3-411.7 m



Volcaniclastic breccia and sandstone

Breccia bed at least 61 cm thick occurs at top of core; breccia is comprised of altered vesicular basalt clasts averaging 3-5 mm in diameter with largest clast about 1 cm by 1.5 cm diameter; clasts are various shades of dark reddish brown and are angular or subangular, some are subrounded; matrix is lt. gray calcite and zeolite. Six beds of volcaniclastic ss occur in the 2-22-92 cm interval interbedded marly limestone and calcareous claystone; ss is virtually a finer-grained equivalent of the breccia; ss beds range from very fine to coarse; beds from very fine to medium sand-size are mostly comprised of single crystals of pyroxene, hornblende, and zeolite (probably amygdaloidal), beds of med. to coarse sand-size contain lithic fragments of altered vesicular basalt; ss beds are mostly shades of reddish brown and are in sharp contact with the calcareous interbeds, ss beds are 1 to 8 cm thick with possiblity of a 20 cm thick bed in a disturbed interval (2-31-51 cm).

Marly limestone and calcareous claystone

Seven beds occur in the 2-20-100 cm interval interbedded with the volcaniclastics; beds are various shades of lt. brn.; most are mod. mottled; scattered dendrites, some along bedding planes; $CaCO_3$ content averages about 30%, ∴ beds are on borderline between marly ls and calcareous claystone; bed thickness is 2-10 cm; contact with underlying nonindurated variegated silty clay is gradational over the 2-81-108 cm interval; these interbeds are laminated and most are cross laminated.

Zeolitic silty clay, variegated (2-100 cm to 5-71 cm) mostly shades of reddish brn. and brn.; firm, but plastic; many intervals diffusely laminated with color contacts usually extremely gradational, rare cross laminations at 3-60 cm, 4-35 cm, and 5-36 cm. Slight to moderate diffuse mottling in some intervals; rare black dendrites along some bedding planes and vertical in some intervals, e.g. 3-45-75 cm; 1 to 2 mm thick black Mn oxide layer parallel to bedding at 5-42 cm; numerous coarser stringers and thin (< 1 cm thick) interbeds occur throughout main lith, most are shades of dark grayish brn. and are enriched in silt and fine sand-sized zeolite clasts; contact with overlying indurated beds is gradational over the 2-81-108 cm interval, contact with underlying dark bluish gray clay is at 5-71 cm and is sharp.

Smear Summary of Major lith (7 slides)

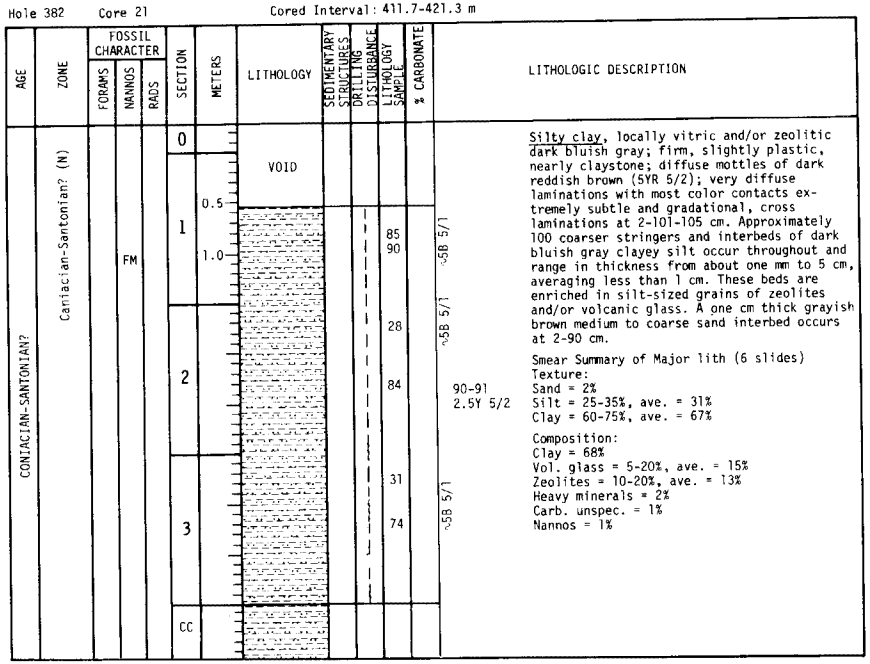
Hole 382 Core 21 Cored Interval: 411.7-421.3 m



Silty clay, locally vitric and/or zeolitic dark bluish gray; firm, slightly plastic, nearly claystone; diffuse mottles of dark reddish brown (5YR 5/2); very diffuse laminations with most color contacts extremely subtle and gradational, cross laminations at 2-101-105 cm. Approximately 100 coarser stringers and interbeds of dark bluish gray clayey silt occur throughout and range in thickness from about one mm to 5 cm, averaging less than 1 cm. These beds are enriched in silt-sized grains of zeolites and/or volcanic glass. A one cm thick grayish brown medium to coarse sand interbed occurs at 2-90 cm.

Smear Summary of Major lith (6 slides)

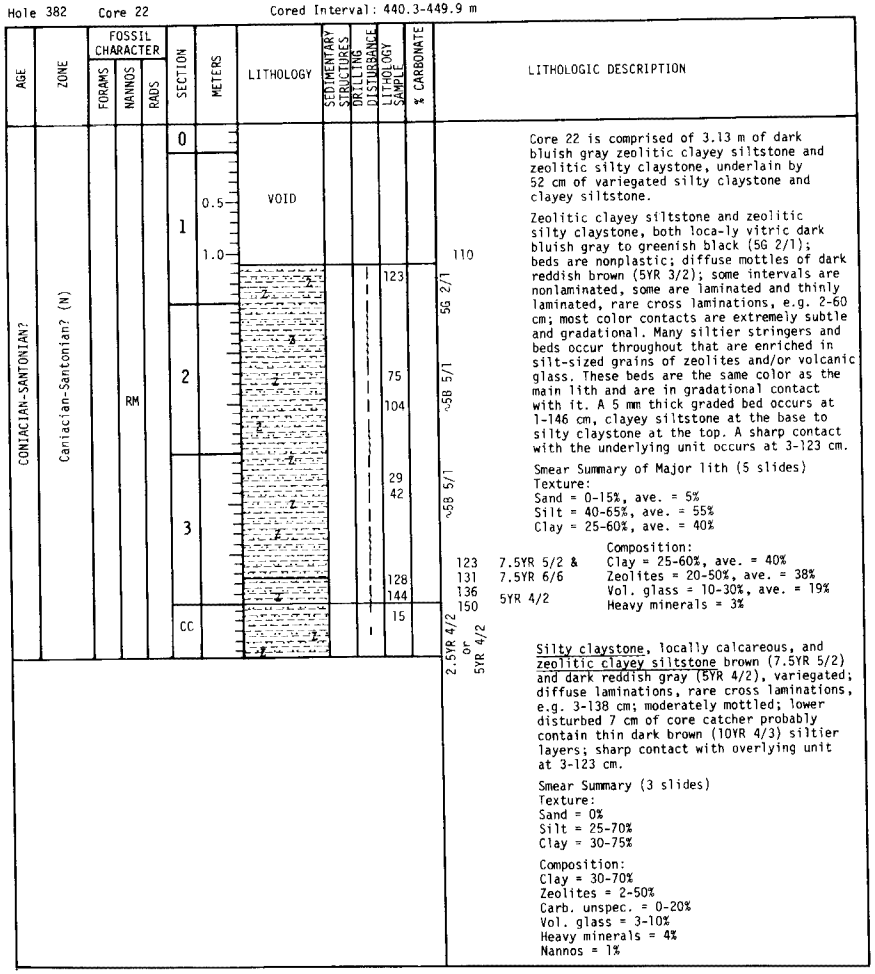
Carb. unspec. = 1%
Nannos = 1%

Hole 382 Core 22 Cored Interval: 440.3-449.9 m



Core 22 is comprised of 3.13 m of dark bluish gray zeolitic clayey siltstone and zeolitic silty claystone, both loca-ly vitric dark bluish gray to greenish black (5G 2/1); beds are nonplastic; diffuse mottles of dark reddish brown (5YR 3/2); some intervals are nonlaminated, some are laminated and thinly laminated, rare cross laminations, e.g. 2-60 cm; most color contacts are extremely subtle and gradational. Many siltier stringers and beds occur throughout that are enriched in silt-sized grains of zeolites and/or volcanic glass. These beds are the same color as the main lith and are in gradational contact with it. A 5 mm thick graded bed occurs at 1-146 cm, clayey siltstone at the base to silty claystone at the top. A sharp contact with the underlying unit occurs at 3-123 cm.

Smear Summary of Major lith (5 slides)
Texture:
Sand = 0-15%, ave. = 5%
Silt = 40-65%, ave. = 55%
Clay = 25-60%, ave. = 40%

Composition:
Clay = 25-60%, ave. = 40%
Zeolites = 20-50%, ave. = 38%
Vol. glass = 10-30%, ave. = 19%
Heavy minerals = 3%

Silty claystone, locally calcareous, and zeolitic clayey siltstone brown (7.5YR 5/2) and dark reddish gray (5YR 4/2), variegated; diffuse laminations, rare cross laminations, e.g. 3-138 cm; moderately mottled; lower disturbed 7 cm of core catcher probably contain thin dark brown (10YR 4/3) siltier layers; sharp contact with overlying unit at 3-123 cm.

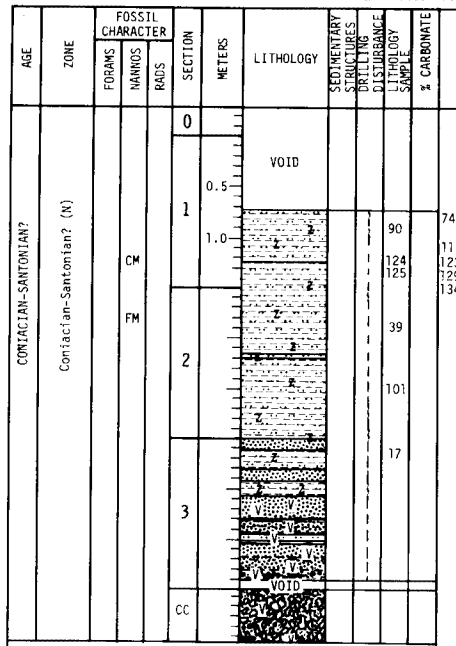
Hole 382 Core 23 Cored Interval: 468.9-478.4 m



LITHOLOGIC DESCRIPTION

Zeolitic silty claystone (1-74 cm to 1-123 cm)
Medium bluish gray (5B 5/1), diffuse mottles and laminations of shades of bluish gray and weak red; this 49 cm interval is virtually identical in appearance and composition with dark bluish gray interval from 20-5-71 cm to 22-3-123 cm, i.e. mostly clay and zeolites with virtually no carbonate.

Zeolitic silty claystone and zeolitic clayey siltstone (1-123 cm to 3-56 cm)
These lith types comprise about 75% of this 2.33 m interval with lith types described below comprising 25%. Mostly brown (10YR 5/3) and reddish brown (2.5YR 4/4); intervals that are nonlaminated alternate with intervals with diffiuse laminations and occasional cross laminations, e.g. at 1-123-129 cm and 2-103 cm. Coarser stringers and thin (<1 cm thick) interbeds of siltstone and fine ss occur throughout, most are shades of dark brown and dark grayish brown. Altered basalt frags up to 4 mm diameter occur in claystone at 3-48 cm. A 1 cm thick graded ss bed occurs at 2-120 cm with coarse sand at base in sharp contact with underlying silty claystone and medium sand at top in gradational contact with overlying silty claystone. Thicker interbeds of coarser volcaniclastic siltstone and ss as described below occur at 2-66-70 cm, 2-136-138 cm, 3-0-12 cm, and 3-31-40 cm, most appear to be in erosional contact with underlying silty claystone and clayey siltstone.

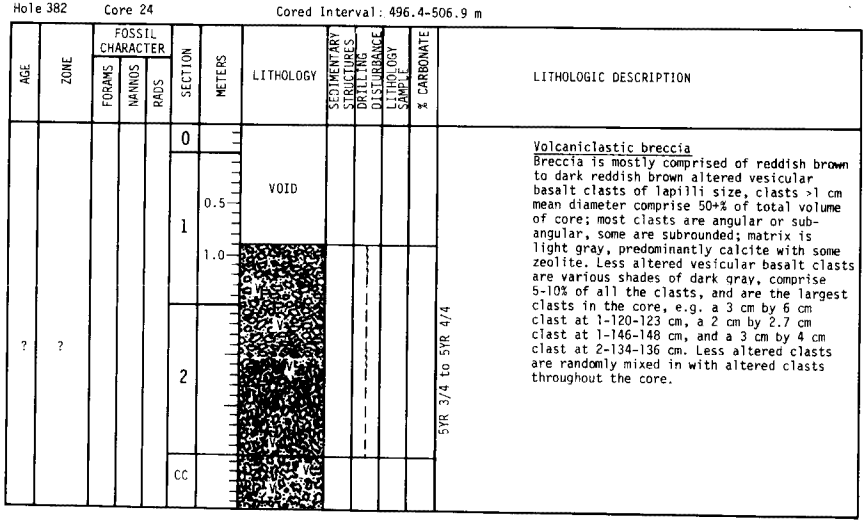
Smear Summary (4 slides)

Texture:	Composition:	
Sand = 0-10%	Clay = 45-50%	Heavy minerals = 5%
Silt = 40-50%	Zeolites = 20-40%	Carb. unspec. = 4%
Clay = 45-50%	Vol. glass = 10%	Nannos = 1%

Volcaniclastic siltstone and sandstone (3-56 cm to 3-130 cm)
These lith types occur in beds up to 23 cm in thickness and comprise about 90% of this 74 cm interval with lith types as described above comprising 10%. Mostly shades of grayish brn., grains mostly silt to fine sand-size except in a crudely graded, poorly sorted interval at 3-118-130 cm in which the upper portion is mainly silt-size and in gradational contact with overlying very fine ss and the lower portion is coarse sand-size and in gradational contact with underlying volcaniclastic breccia. Some beds are moderately burrow mottled with burrow fillings of reddish brown claystone. Thin sections show that the beds have a clay matrix with clastis in the upper portion of the interval mostly comprised of single crystals of plagioclase, pyroxene, and hornblende, and rounded amygdule-like grains of zeolites. The coarser clasts closer to the contact with the underlying breccia are mostly altered vesicular basalt fragments.

Volcaniclastic breccia (30 cm of sample from 3-130 cm to bottom of core catcher)
Breccia is comprised of reddish brown altered vesicular basalt clasts of lapilli size (max. size is 1 cm by 1 cm) in a light gray matrix of calcite and zeolites, most clasts are angular or subangular, some are subrounded, bedding is distinguished by intervals of different average clast size and appears to be horizontal in 3-130-140 cm and dipping at about 10° in the core catcher sample. Contact with overlying volcaniclastic sandstone is gradational.

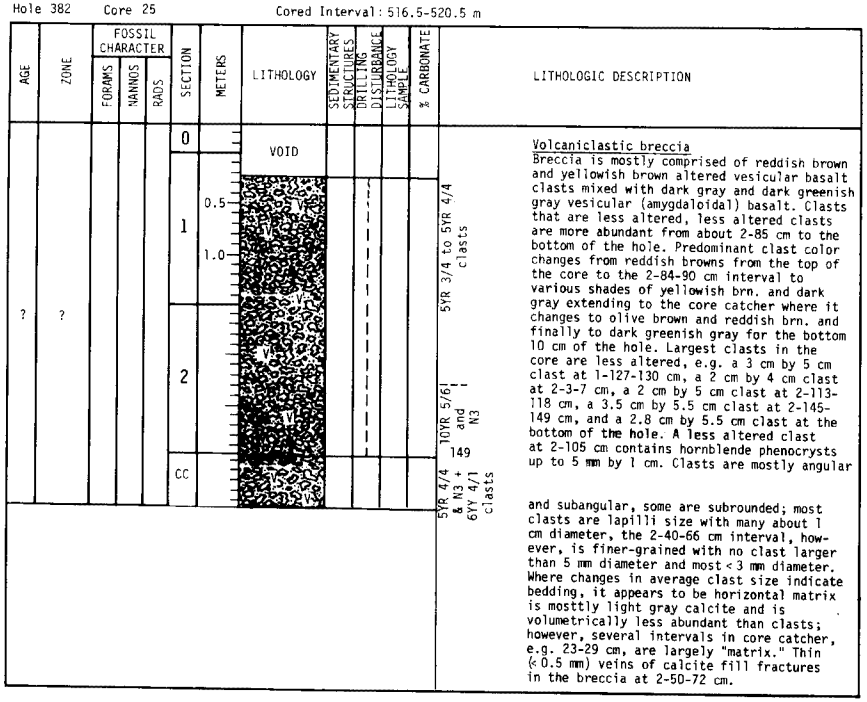
Hole 382 Core 24 Cored Interval: 496.4-506.9 m



LITHOLOGIC DESCRIPTION

Volcaniclastic breccia
Breccia is mostly comprised of reddish brown to dark reddish brown altered vesicular basalt clasts of lapilli size, clasts >1 cm mean diameter comprise 50+% of total volume of core; most clasts are angular or sub-angular, some are subrounded; matrix is light gray, predominantly calcite with some zeolite. Less altered vesicular basalt clasts are various shades of dark gray, comprise 5-10% of all the clasts, and are the largest clasts in the core, e.g. a 3 cm by 6 cm clast at 1-120-123 cm, a 2 cm by 2.7 cm clast at 1-146-148 cm, and a 3 cm by 4 cm clast at 2-134-136 cm. Less altered clasts are randomly mixed in with altered clasts throughout the core.

Hole 382 Core 25 Cored Interval: 516.5-520.5 m



Volcaniclastic breccia
Breccia is mostly comprised of reddish brown and yellowish brown altered vesicular basalt clasts mixed with dark gray and dark greenish gray vesicular (amygdaloidal) basalt. Clasts that are less altered, less altered clasts are more abundant from about 2-85 cm to the bottom of the hole. Predominant clast color changes from reddish browns from the top of the core to the 2-84-90 cm interval to various shades of yellowish brn. and dark gray extending to the core catcher where it changes to olive brown and reddish brn. and finally to dark greenish gray for the bottom 10 cm of the hole. Largest clasts in the core are less altered, e.g. a 3 cm by 5 cm clast at 1-127-130 cm, a 2 cm by 4 cm clast at 2-3-7 cm, a 2 cm by 5 cm clast at 2-113-118 cm, a 3.5 cm by 5.5 cm clast at 2-145-149 cm, and a 2.8 cm by 5.5 cm clast at the bottom of the hole. A less altered clast at 2-105 cm contains hornblende phenocrysts up to 5 mm by 1 cm. Clasts are mostly angular and subangular, some are subrounded; most clasts are lapilli size with many about 1 cm diameter, the 2-40-66 cm interval, however, is finer-grained with no clast larger than 5 mm diameter and most < 3 mm diameter. Where changes in average clast size indicate bedding, it appears to be horizontal matrix is mosttly light gray calcite and is volumetrically less abundant than clasts; however, several intervals in core catcher, e.g. 23-29 cm, are largely "matrix." Thin (< 0.5 mm) veins of calcite fill fractures in the breccia at 2-50-72 cm.

LEG 43 SITE 383

SITE SUMMARY SHEET

POSITION: Latitude: 39°14.88'N Longitude: 53°21.18'W

Water depth (sea level): 5283 corrected meters, echo sounding

Bottom felt at: 5277 meters, drill pipe Penetration: 120.3 meters

Number of holes: 1 Number of cores: 2

Total length of cored section: 120.3 meters

Total core recovered: 4.9 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 63.3 meters Nature: Coarse sand

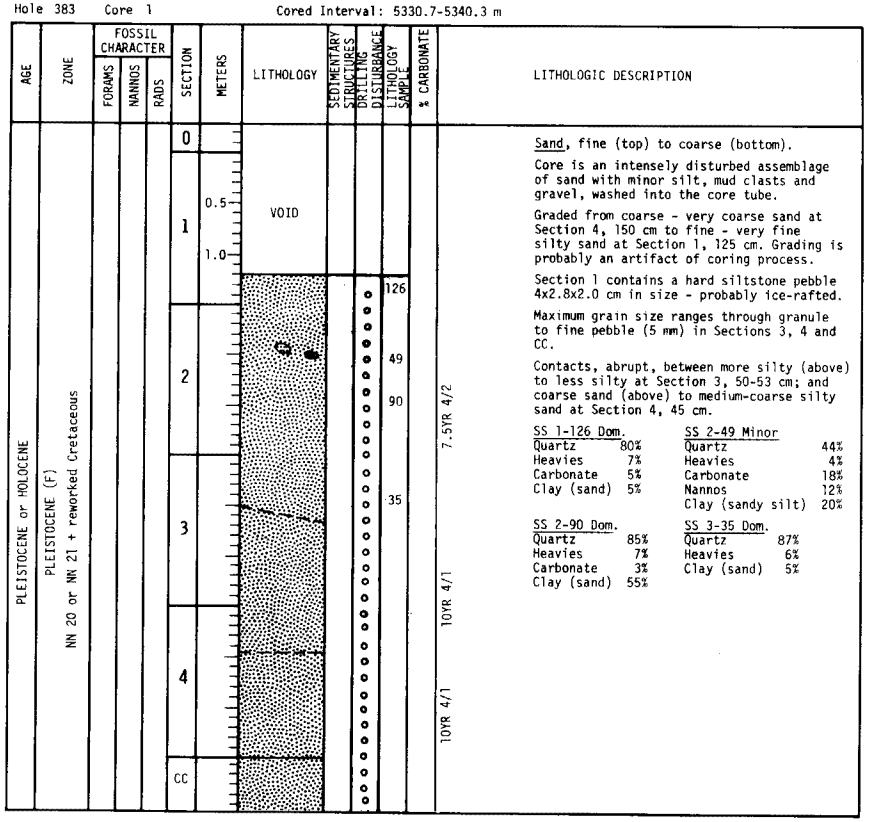
Age: Pleistocene

BASEMENT: Not reached

PRINCIPAL RESULTS:

Site 383 was drilled to 120 meters in the Sohm abyssal plain before deteriorating hole conditions and the risk of losing the bottom-hole assembly in caving sands forced abandonment. The single core recovered consists of 4.9 meters of graded Pleistocene sand. The grading here is undoubtedly an artifact produced by flushing of sand into the core barrel during a break in circulation.

Hole 383 Core 1 Cored Interval: 5330.7-5340.3 m



Sand, fine (top) to coarse (bottom).

Core is an intensely disturbed assemblage of sand with minor silt, mud clasts and gravel, washed into the core tube.

Graded from coarse - very coarse sand at Section 4, 150 cm to fine - very fine silty sand at Section 1, 125 cm. Grading is probably an artifact of coring process.

Section 1 contains a hard siltstone pebble 4x2.8x2.0 cm in size - probably ice-rafted.

Maximum grain size ranges through granule to fine pebble (5 mm) in Sections 3, 4 and CC.

Contacts, abrupt, between more silty (above) to less silty at Section 3, 50-53 cm; and coarse sand (above) to medium-coarse silty sand at Section 4, 45 cm.

DEEP SEA DRILLING PROJECT

LEG 43 SITE 384

SITE SUMMARY SHEET

POSITION: Latitude: 40°21.65'N Longitude: 51°39.80'W

Water depth (sea level): 3909 corrected meters, echo sounding

Bottom felt at: 3920 meters, drill pipe Penetration: 330.3 meters

Number of holes: 1 Number of cores: 22

Total length of cored section: 195.3 meters

Total core recovered: 110.52 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 324.5 meters Nature: Shallow water limestone

Age: Aptian or older Measured velocity: 2.05 km/s

BASEMENT:

Depth subbottom: 324.8 meters Nature: Vesicular basalt

Velocity range: 3.46-4.32 km/s

PRINCIPAL RESULTS:

A 330.3-meter section was drilled on the "J-anomaly" ridge where it emerges above the lower continental rise south of the Grand Banks. The hole bottomed in altered vesicular basalt which plugged the bit and jammed the core barrel in the drill string. We anticipated that a prominent reflector within the acoustically nonlaminated sediments covering the ridge might correlate with Horizon A, which previously had been identified only to the south of the Sohm Abyssal Plain. Reduced drilling rates and recovery of chert fragments and silicified limestone of lower Eocene age at the level of the reflector confirmed this evaluation. The section drilled consists of the following three major lithofacies (top to bottom): (1) marly nanno ooze, nanno ooze, nanno chalk and foraminiferal nanno chalk of middle Eocene to lower Maestrichtian age (50-200 meters). This calcareous unit contains excellently preserved foraminifers and nannoplankton in a nearly continuous sequence across the Cretaceous-Tertiary transition, as well as an excellent assemblage of radiolarians down to the lower

Paleocene. High carbonate content (50-100%) and nearly uniform sedimentation rates (0.5 g/cm^2/k.y. for Cretaceous and Paleocene, 1.5 g/cm^2/k.y. for Eocene) indicate deposition in a quiescent environment, probably in relatively shallow water, well above the CCD. We find no evidence for the hypothetical Maestrichtian/Paleocene rise in CCD. (2) ?Coniacian-Santonian to Aptian shallow-water bioclastic limestones with minor interbedded calcareous clays (200-325 m), indicating more than 4000 meters subsidence for this part of the "J-anomaly" ridge in the last 80-87 m.y. (3) The bioclastic limestones are underlain below 325 meters by highly vesicular, weathered basalt, apparently formed as a subaerial or shallow-water flow. The Aptian age of the overlying sediment indicates that anomaly M-1 (J-4) is at least 105 m.y. old. A total of 2.36 meters of basalt was cored, representing portions of two flows.

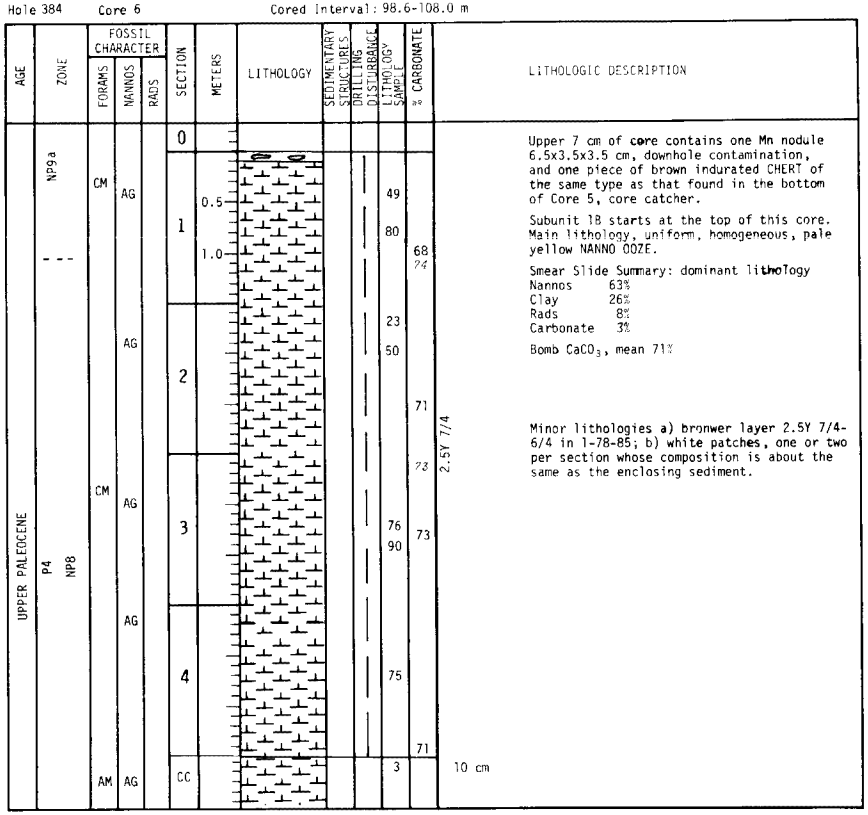
CHERT layer, brecciated by drilling, from 3-126-131, brown 7.5YR 5/2 to yellowish brown 10YR 5/6.

NANNO CHALK layer 11 cm thick comprising top of core catcher sample yellow 10YR 7/4. Beneath this is 11 cm of dark brown 10YR 4/3 to brown 10YR 5/3, slightly mottled, irregularly laminated, indurated, SILICEOUS LIMESTONE grading downwards to CHERT.

Two manganese nodules and a pebble were found in the zone 1-11-17, probable downhole contamination; also small nodules (1.5 and 2 cm long) and pebble found at 3-100-107.

The chert, chalk and limestone in the lower part of the section probably are part of the Horizon A reflector. A hiatus of over 3 m.y. is found between Core 5 and Core 6 and these hard lithologies mark the base of Unit 1A in this section.

Hole 384 Core 6 Cored Interval: 98.6-108.0 m



Upper 7 cm of core contains one Mn nodule 6.5x3.5x3.5 cm, downhole contamination, and one piece of brown indurated CHERT of the same type as that found in the bottom of Core 5, core catcher.

Subunit 1B starts at the top of this core. Main lithology, uniform, homogeneous, pale yellow NANNO OOZE.

Smear Slide Summary: dominant lithology

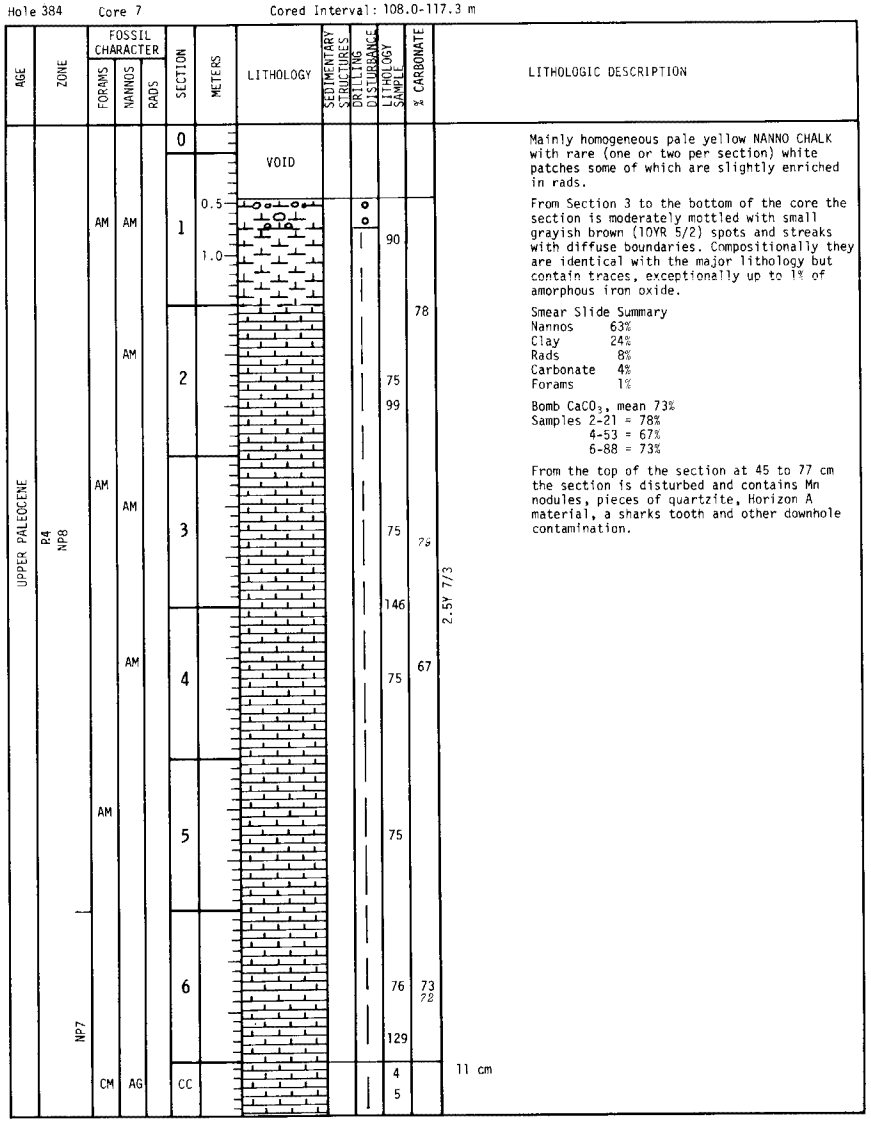
Bomb $CaCO_3$, mean 71%

Minor lithologies a) bronwer layer 2.5Y 7/4-6/4 in 1-78-85; b) white patches, one or two per section whose composition is about the same as the enclosing sediment.

Hole 384 Core 7 Cored Interval: 108.0-117.3 m



Mainly homogeneous pale yellow NANNO CHALK with rare (one or two per section) white patches some of which are slightly enriched in rads.

From Section 3 to the bottom of the core the section is moderately mottled with small grayish brown (10YR 5/2) spots and streaks with diffuse boundaries. Compositionally they are identical with the major lithology but contain traces, exceptionally up to 1% of amorphous iron oxide.

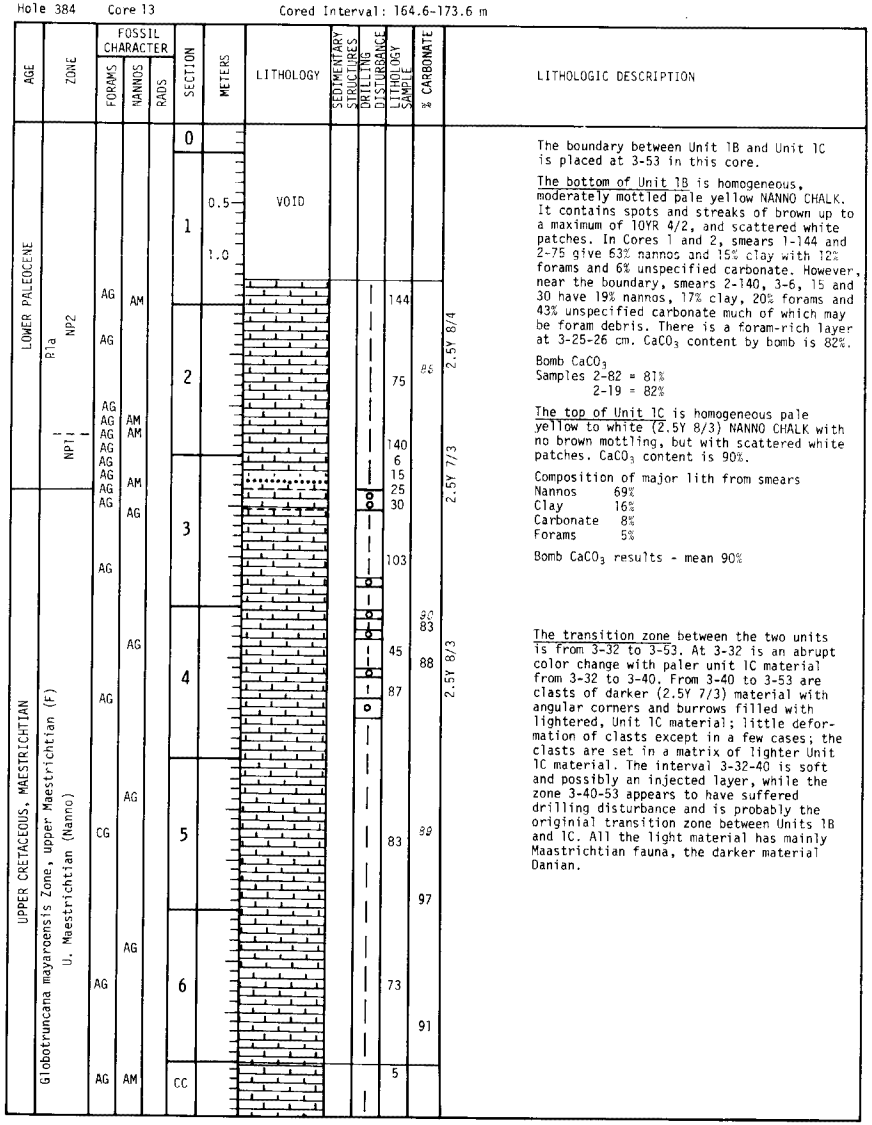
This is the first core going up section, in which rads are found in appreciable quantity.
Patches of softer chalk to ooze between harder fractured pieces of chalk may represent drilling-disturbed, softened or injected layers. They may comprise 50% of the section, are in units generally thinner than 20 cm, and are not always easy to delimit.

Hole 384 Core 13 Cored Interval: 164.6-173.6 m



The boundary between Unit 1B and Unit 1C is placed at 3-53 in this core.

The bottom of Unit 1B is homogeneous, moderately mottled pale yellow NANNO CHALK. It contains spots and streaks of brown up to a maximum of 10YR 4/2, and scattered white patches. In Cores 1 and 2, smears 1-144 and 2-75 give 63% nannos and 15% clay with 12% forams and 6% unspecified carbonate. However, near the boundary, smears 2-140, 3-6, 15 and 30 have 19% nannos, 17% clay, 20% forams and 43% unspecified carbonate much of which may be foram debris. There is a foram-rich layer at 3-25-26 cm. $CaCO_3$ content by bomb is 82%.

Bomb $CaCO_3$
Samples 2-82 = 81%
2-19 = 82%

The top of Unit 1C is homogeneous pale yellow to white (2.5Y 8/3) NANNO CHALK with no brown mottling, but with scattered white patches. $CaCO_3$ content is 90%.

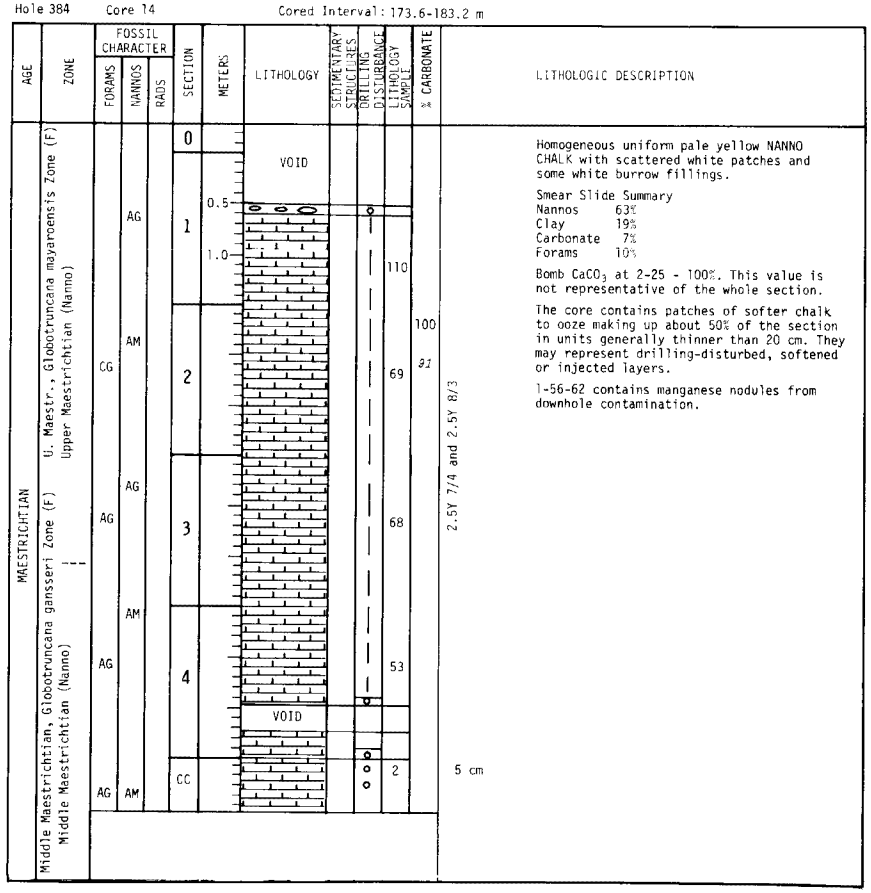
Composition of major lith from smears

Nannos	69%
Clay	16%
Carbonate	8%
Forams	5%

Bomb $CaCO_3$ results - mean 90%

The transition zone between the two units is from 3-32 to 3-53. At 3-32 is an abrupt color change with paler unit 1C material from 3-32 to 3-40. From 3-40 to 3-53 are clasts of darker (2.5Y 7/3) material with angular corners and burrows filled with lightered, Unit 1C material; little deformation of clasts except in a few cases; the clasts are set in a matrix of lighter Unit 1C material. The interval 3-32-40 is soft and possibly an injected layer, while the zone 3-40-53 appears to have suffered drilling disturbance and is probably the originial transition zone between Units 1B and 1C. All the light material has mainly Maastrichtian fauna, the darker material Danian.

Hole 384 Core 14 Cored Interval: 173.6-183.2 m



Homogeneous uniform pale yellow NANNO CHALK with scattered white patches and some white burrow fillings.

TEXTURE: Hypocrystalline. GRANULARITY: Porphyritic, amygdalogidal. FABRIC: Pliotaxitic (Diabasic) with minor fluxion of groundmass plagioclase. PHENOCRYSTS: 1) Pyroxene-colorless to pale purplish brown, subhedral, broken and corroded prismatic crystals of augite (N=1.70; 0.5-1.4 mm; 8-15%) partly altered to uralite (tremolite plus minor amounts of another amphibole phase) as single crystals or crystal aggregates plus chlorite with or without calcite. Alteration greatest along cleavage planes and is accompanied by irregular bleaching of the crystal flecked with small patches of magnetite. 2) Scarce patches of bowlingite suggest former existence of an olivine phenocryst phase. 3) Plagioclase (An 62) phenocrysts are smaller (0.5-1.0 mm) and rare (< 1%). The GROUNDMASS: consists of pyroxene (10-20%) altered partly to chlorite, polkilitic plagioclase (An 51; 60-70%) partially altered to zeolite plus chlorite, and rare brown glass, mostly devitrified. Patches of interstitial chlorite, smectite, plus zeolite probably represent former glass. ALTERATION: As noted above. Many alteration products, especially calcite, chlorite, and zeolite fill vesicles commonly vesicles are lined with opaques. Amygdules average 10-20% in cross section. The lower dark yellowish brown unit starting at 74 cm in Section 2 contains relict glass and opaques, more oxidized iron, less chlorite, and fresher plagioclase.

DEEP SEA DRILLING PROJECT

LEG 43 SITE 385

SITE SUMMARY SHEET

POSITION: Latitude: 37°22.17'N Longitude: 60°09.45'W

Water depth (sea level): 4936 corrected meters, echo sounding

Bottom felt at: 4966 meters, drill pipe Penetration: 392.9 meters

Number of holes: 1 Number of cores: 24

Total length of cored section: 227.6 meters

Total core recovered: 63.43 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 392.9 meters Nature: Volcaniclastic breccia

Age: Lower Maestrichtian or older

BASEMENT*:

Depth subbottom: 392.9 meters Nature: Volcaniclastic breccia

PRINCIPAL RESULTS:

Site 385 was drilled 392.9 meters through a transparent sediment layer and into the underlying volcaniclastic apron forming the north flank of Vogel Seamount. Horizon A can be traced from beneath the Sohm Abyssal Plain to the drill site, where it occurs 0.2 s subbottom and 0.17 s above the volcaniclastic apron. A total of 24 cores (227.6 m) were taken; the low overall recovery (63.4 m) reflects poor coring performance in cherts and uncemented volcaniclastic sands and gravels.

Formations encountered are as follows: A spot-cored section of Pleistocene to lower Miocene clays overlies continuously cored lower-middle to upper-lower Eocene clays and chert (138-165 m subbottom) containing rich and well preserved radiolarian fauna. Horizon A is correlated with an alternating chert and radiolarian ooze interval approximately 153-165 meters subbottom. The section from 165 to 206 meters consists of zeolitic silty clay containing poorly preserved and unidentified radiolarian assemblages. Lower Danian to Maestrichtian

marly ooze (206-251 m) overlies volcanic sediments older than mid or lower Maestrichtian that continue to 393 meters. A thin (18 cm) layer of aphanitic basalt was cored at 283 meters; this may be either a sill or a flow, although the possiblity that it is a displaced boulder cannot be excluded. The deepest volcanic material penetrated is a volcaniclastic breccia very similar to those recovered at Site 382 on Nashville Seamount.

Unfortunately, the volcanogenic unit is unfossiliferous except for a few long-ranging benthonic Foraminifera, and the deepest dates in the hole are for the marly ooze above the unit. However, we can make some meaningful estimates of the ages from extrapolated and assumed sedimentation rates. If sedimentation rates were fairly uniform in the marly ooze unit, then the top of the volcanogenic debris probably dates from the late Campanian. A good estimate for accumulation rates in the volcanogenic unit is probably that determinated at Site 382 (12 m/m.y.). This places the top of the volcaniclastic breccia at Site 385 within the Santonian at about 81-82 m.y. The similar spacing in time of the two peak volcanic phases at Sites 382 and 385 is suggestive that in reality they may be coeval. In fact, by using a slightly reduced, but reasonable, sedimentation rate (8 m/m.y.) for the volcanogenic section at Site 385, we can bring the peak episodes almost exactly into phase. Thus, there exists a strong possibility that volcanism at Nashville and Vogel Seamounts was essentially synchronous in the late Cretaceous, rather than migratory.

Hole 385 Core 1 Cored Interval: 22.3-31.8 m

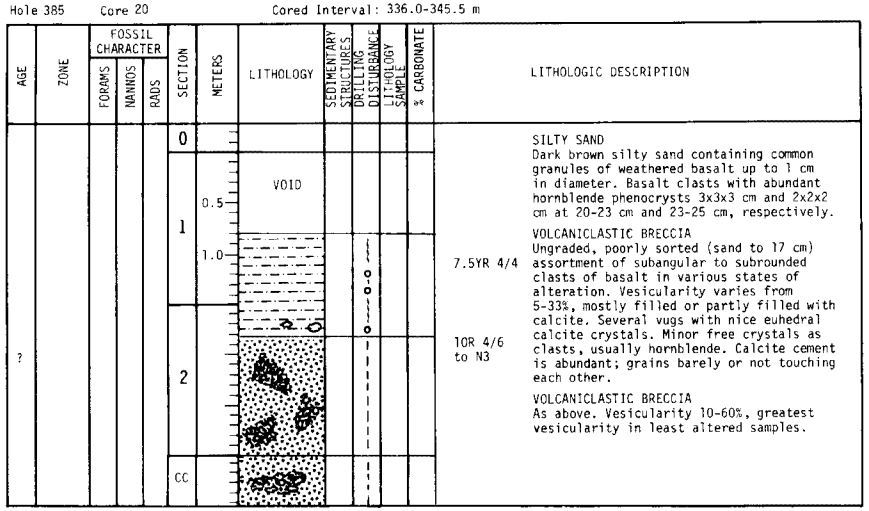
CLAYEY SILT
Loose clayey silt intensely mottled with 10R 4/6, 10YR 4/4, and 5Y 6/3 containing common to abundant granules of very altered basalt.

Smear Slide Summary (2 slides)

Clay	30%
Altered ash	35%
Vol. glass	20%
Opaques	15%

GRANULE SAND
Fragments of very altered basalt up to 0.1 cm. Composition like that above, but less clay. Three fragments of weak red altered BASALT.

Hole 385 Core 20 Cored Interval: 336.0-345.5 m

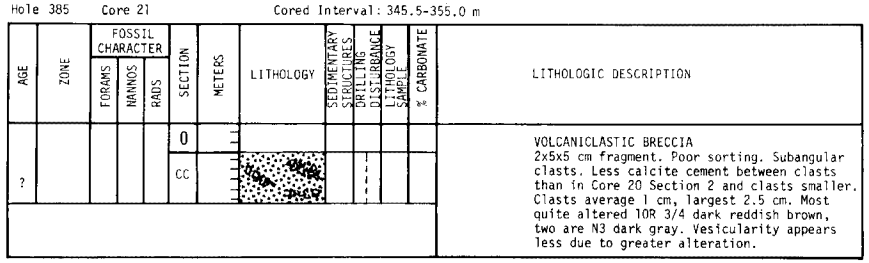


SILTY SAND
Dark brown silty sand containing common granules of weathered basalt up to 1 cm in diameter. Basalt clasts with abundant hornblende phenocrysts 3x3x3 cm and 2x2x2 cm at 20-23 cm and 23-25 cm, respectively.

VOLCANICLASTIC BRECCIA
Ungraded, poorly sorted (sand to 17 cm) assortment of subangular to subrounded clasts of basalt in various states of alteration. Vesicularity varies from 5-33%, mostly filled or partly filled with calcite. Several vugs with nice euhedral calcite crystals. Minor free crystals as clasts, usually hornblende. Calcite cement is abundant; grains barely or not touching each other.

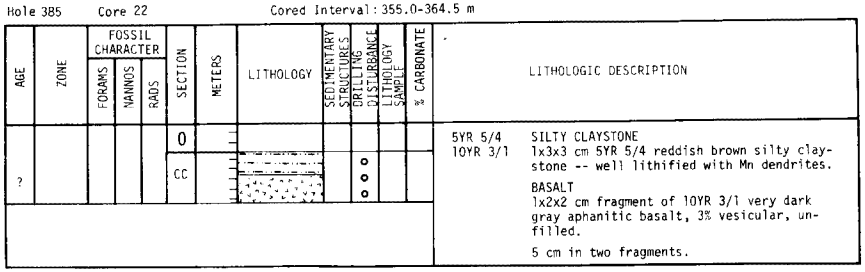
VOLCANICLASTIC BRECCIA
As above. Vesicularity 10-60%, greatest vesicularity in least altered samples.

Hole 385 Core 21 Cored Interval: 345.5-355.0 m



VOLCANICLASTIC BRECCIA
2x5x5 cm fragment. Poor sorting. Subangular clasts. Less calcite cement between clasts than in Core 20 Section 2 and clasts smaller. Clasts average 1 cm, largest 2.5 cm. Most quite altered 10R 3/4 dark reddish brown, two are N3 dark gray. Vesicularity appears less due to greater alteration.

Hole 385 Core 22 Cored Interval: 355.0-364.5 m

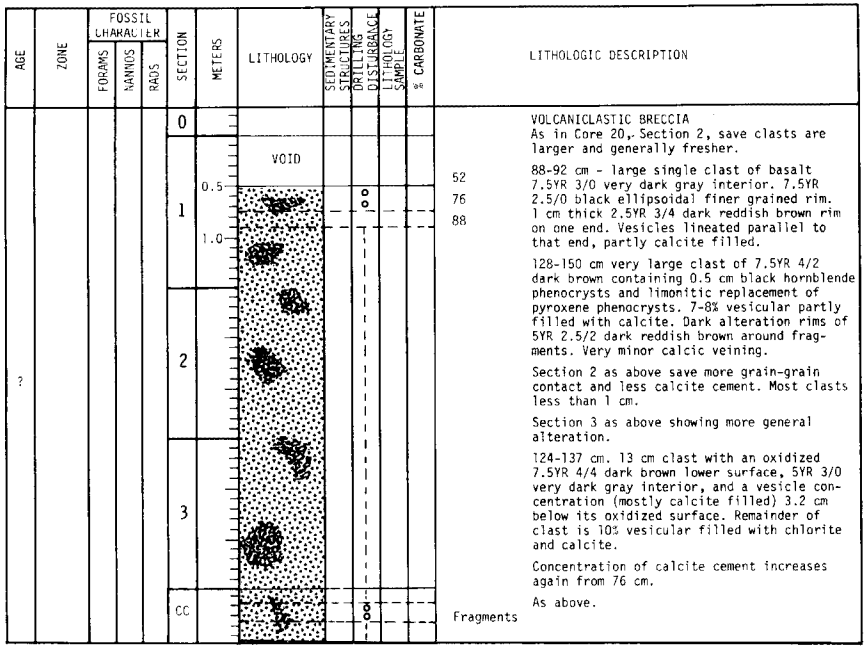


SILTY CLAYSTONE
1x3x3 cm 5YR 5/4 reddish brown silty claystone -- well lithified with Mn dendrites.

BASALT
1x2x2 cm fragment of 10YR 3/1 very dark gray aphanitic basalt, 3% vesicular, unfilled.

5 cm in two fragments.

Hole 385 Core 23 Cored Interval: 374.0-383.5 m



VOLCANICLASTIC BRECCIA
As in Core 20, Section 2, save clasts are larger and generally fresher.

88-92 cm - large single clast of basalt 7.5YR 3/0 very dark gray interior. 7.5YR 2.5/0 black ellipsoidal finer grained rim. 1 cm thick 2.5YR 3/4 dark reddish brown rim on one end. Vesicles lineated parallel to that end, partly calcite filled.

128-150 cm very large clast of 7.5YR 4/2 dark brown containing 0.5 cm black hornblende phenocrysts and limonitic replacement of pyroxene phenocrysts. 7-8% vesicular partly filled with calcite. Dark alteration rims of 5YR 2.5/2 dark reddish brown around fragments. Very minor calcic veining.

Section 2 as above save more grain-grain contact and less calcite cement. Most clasts less than 1 cm.

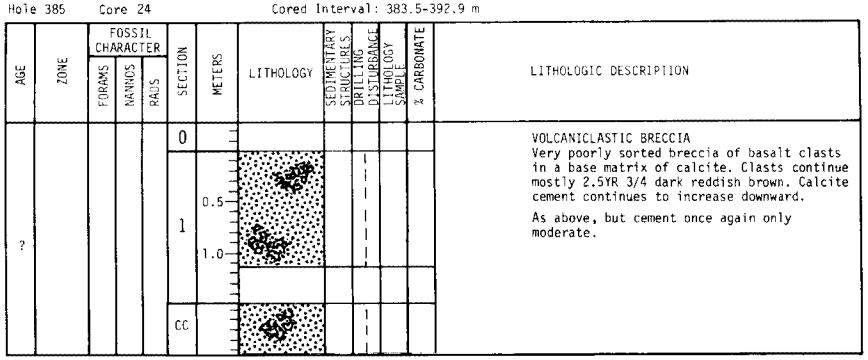
Section 3 as above showing more general alteration.

124-137 cm. 13 cm clast with an oxidized 7.5YR 4/4 dark brown lower surface, 5YR 3/0 very dark gray interior, and a vesicle concentration (mostly calcite filled) 3.2 cm below its oxidized surface. Remainder of clast is 10% vesicular filled with chlorite and calcite.

Concentration of calcite cement increases again from 76 cm.

As above.

Hole 385 Core 24 Cored Interval: 383.5-392.9 m



VOLCANICLASTIC BRECCIA
Very poorly sorted breccia of basalt clasts in a base matrix of calcite. Clasts continue mostly 2.5YR 3/4 dark reddish brown. Calcite cement continues to increase downward.

As above, but cement once again only moderate.

DEEP SEA DRILLING PROJECT

LEG 43 SITE 386

SITE SUMMARY SHEET

POSITION: Latitude: 31°11.21'N Longitude: 64°14.94'W

Water depth (sea level): 4792 corrected meters, echo sounding

Bottom felt at: 4793 meters, drill pipe Penetration: 973.8 meters

Number of holes: 1 Number of cores: 66

Total length of cored section: 626.70 meters

Total core recovered: 438.15 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 964.2 meters Nature: Black claystone

Age: Upper Aptian-lowest Albian (103-106.5 m.y.)

Measured velocity: 1.95-2.46 km/s

BASEMENT:

Depth subbottom: 966.2 meters Nature: Basalt

Velocity range: 3.90-4.45 km/s

PRINCIPAL RESULTS:

Site 386 was drilled to a depth of 966.2 meters on the central Bermuda Rise, 140 km SSE of Bermuda. Sixty six cores were taken, of which the lowest recovered 1.90 meters of altered basalt. Basement age was established as upper Aptian-lower Albian on the basis of nannoplankton in the overlying green/black claystones. The section consists of discontinuously cored Pleistocene marly nanno ooze (0-62 m) overlying Pleistocene to lower Miocene zeolitic clays (62-148 m); continuously cored lower Miocene calcareous turbidites grading downward into Oligocene and upper Eocene volcaniclastic turbidites (148-328 m); middle Eocene siliceous (328-410 m) and calcareous (410-482 m) cyclic successions (turbidites?) overlying middle Eocene to Paleocene rad and cherty rad mudstones (482-613 m); upper Maestrichtian to upper Cenomanian multicolored claystone (613-724 m) above upper Cenomanian

to upper Aptian/lower Albian black and green claystones (724-964 m); and basalt (cored from 964-974 m).

Deposition was predominately continuous although highly variable in rate. Short hiatuses are indicated in the mid to late Oligocene and mid to late Eocene; high rates characterize the sapropelic claystones (18 m/m.y.), middle Eocene calcareous-siliceous turbidites (33-47 m/m.y.), late Paleocene to early Eocene radiolarian mudstones (5 to 26 m/m.y.), and volcaniclastic turbidites (19 m/m.y.).

Volcaniclastic turbidites with shallow water detritus indicate the Bermuda volcano was emergent by middle or late Eocene (41 m.y.) but had been leveled by erosion by middle to late Oligocene (22-30 m.y.). This result corroborates the 33 m.y. published date of lamprophyric dikes drilled on Bermuda. A 30-meter section of upper Cenomanian zeolitic multicolored claystone suggests an earlier volcanic phase at 92-96 m.y., possibly correlative with a 90 m.y. drill hole date on Bermuda.

Organic carbon analyses in the sapropelic claystones show carbon maxima (7%) in mid-late Cenomanian and late Aptian/early Albian; this double peaked character of the mid-Cretaceous stagnation possibly correlates with carbon distribution in the black clays of Site 105.

The top of the Oligocene volcaniclastic turbidites is seismically continuous with the Bermuda Pedestal and masks Horizon A at the drill site. Horizon A matches the top of the siliceous mid-Eocene section and a short hiatus. Horizon A* corresponds to the boundary between the Tertiary siliceous claystones and the upper Cretaceous multi-colored claystones.

The upper Aptian-lower Albian date on the basement confirms that crust forming the east flank of the Bermuda Rise was generated at the relatively rapid rate of about 2.5 cm/yr.

The dominant lithology is CLAYSTONE. Essentially dark gray and black, with some minor dark bluish green and greenish black intercalations. The black claystones are mostly homogeneous and faintly laminated and laminated, the greenish varieties are mottled. RAD-SAND layers, ranging in thickness from <1 cm to a few cm, are abundant (as indicated). Besides, fine mud clasts occur in several laminae, and also whitish and yellowish specks of carbonate clasts. PYRITE is abundant throughout, forming large concretions in the lower part of Section 2 and Section 4 (there they are developed at a clay/sand boundary, entering both the lower clay and upper sand layer). Other CONCRETIONS are found in Sections 3 (0-25 cm in claystone, at 95 cm) and 4 (at 35 cm) and are possibly siderite(?).

The dip changes within Section 2 from 10° (in upper half) to horizontal (at 75 cm) to ~5° (in lower half). Within the core, some curved bedding was observed in sandy layers. The dip changes within the entire core several times in the range of 5-~15°.

Dominant lithology is CLAYSTONE with a few thin beds of calcareous claystone and at least two thin beds of siderite claystone with >60% siderite. Through much of the core their are alternations of grayish black (laminated or homogeneous) with grayish blue green to greenish gray (mottled and irregularly laminated) claystone. Recrystallized red sands are abundant. Some layers have flat green mud clasts in the bottom and may be graded.

N1
5Y 4/1-N2

The dominant lithology is CLAYSTONE of mostly very dark colors with prevailing dark gray-black and some small dark bluish green horizons and some olive gray layers. The black layers are mostly homogeneous, laminated and faintly laminated. The bluish-green layers are minor and are faintly mottled and mottled with mostly darker colors.
Black RAD-SAND AND SILTY laminae are common (as indicated in lithologic column) to abundant.
A few laminae are whitish, almost entirely carbonate, CHALK, both from nannos and unspecified.
Some of the rad sand layers contain also very small green mud clasts, some carbonate-rich layers as well.
CONCRETIONS of possibly siderite(?) occur at 30 cm of Section 2, 50 and 65 cm of Section 3, and at 80 cm in Section 4.
It may be noted that some of the rad-sand layers have irregular upper boundaries.
The olive gray layers possibly also contain siderite?.

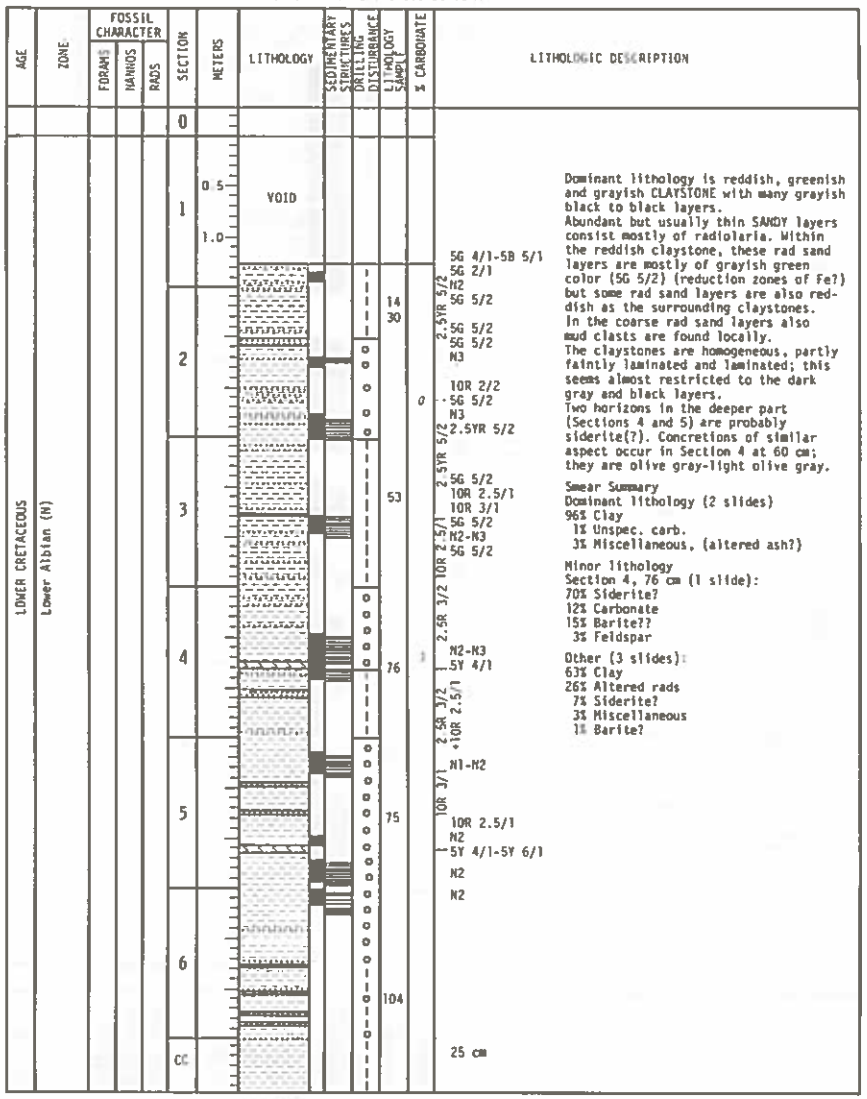
12 cm

Hole 386 Core 64 Cored Interval: 945.3-954.8 m



Dominant lithology is reddish, greenish and grayish CLAYSTONE with many grayish black to black layers.
Abundant but usually thin SANDY layers consist mostly of radiolaria. Within the reddish claystone, these rad sand layers are mostly of grayish green color (5G 5/2) (reduction zones of Fe?) but some rad sand layers are also reddish as the surrounding claystones.
In the coarse rad sand layers also mud clasts are found locally.
The claystones are homogeneous, partly faintly laminated and laminated; this seems almost restricted to the dark gray and black layers.
Two horizons in the deeper part (Sections 4 and 5) are probably siderite(?). Concretions of similar aspect occur in Section 4 at 60 cm; they are olive gray-light olive gray.

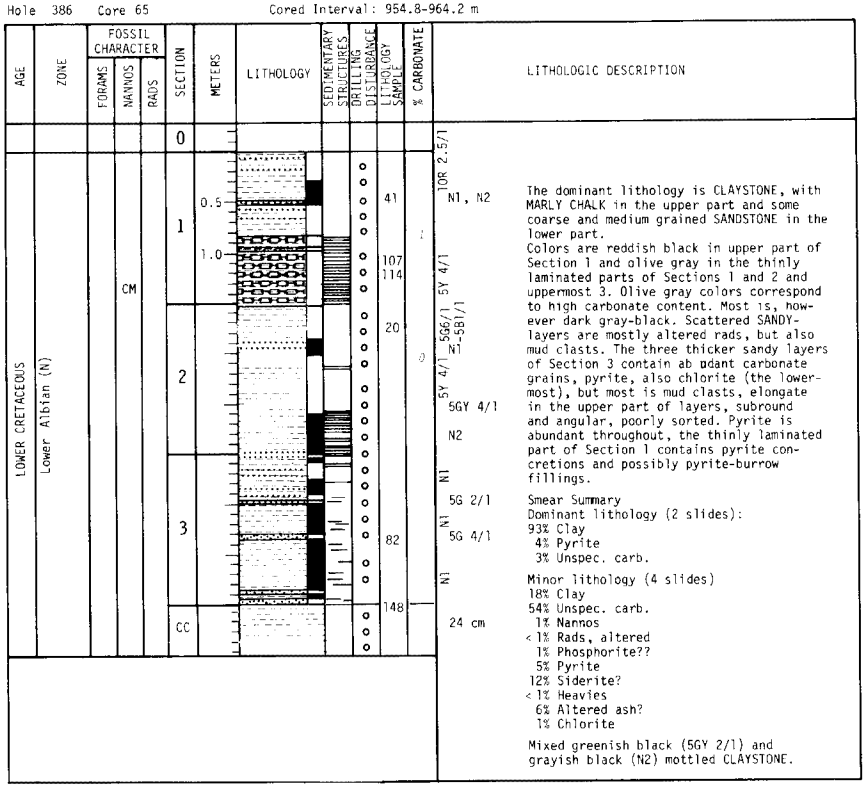
1% Barite?

Hole 386 Core 65 Cored Interval: 954.8-964.2 m



The dominant lithology is CLAYSTONE, with MARLY CHALK in the upper part and some coarse and medium grained SANDSTONE in the lower part.
Colors are reddish black in upper part of Section 1 and olive gray in the thinly laminated parts of Sections 1 and 2 and uppermost 3. Olive gray colors correspond to high carbonate content. Most is, however dark gray-black. Scattered SANDY-layers are mostly altered rads, but also mud clasts. The three thicker sandy layers of Section 3 contain ab ndant carbonate grains, pyrite, also chlorite (the lowermost), but most is mud clasts, elongate in the upper part of layers, subround and angular, poorly sorted. Pyrite is abundant throughout, the thinly laminated part of Section 1 contains pyrite concretions and possibly pyrite-burrow fillings.

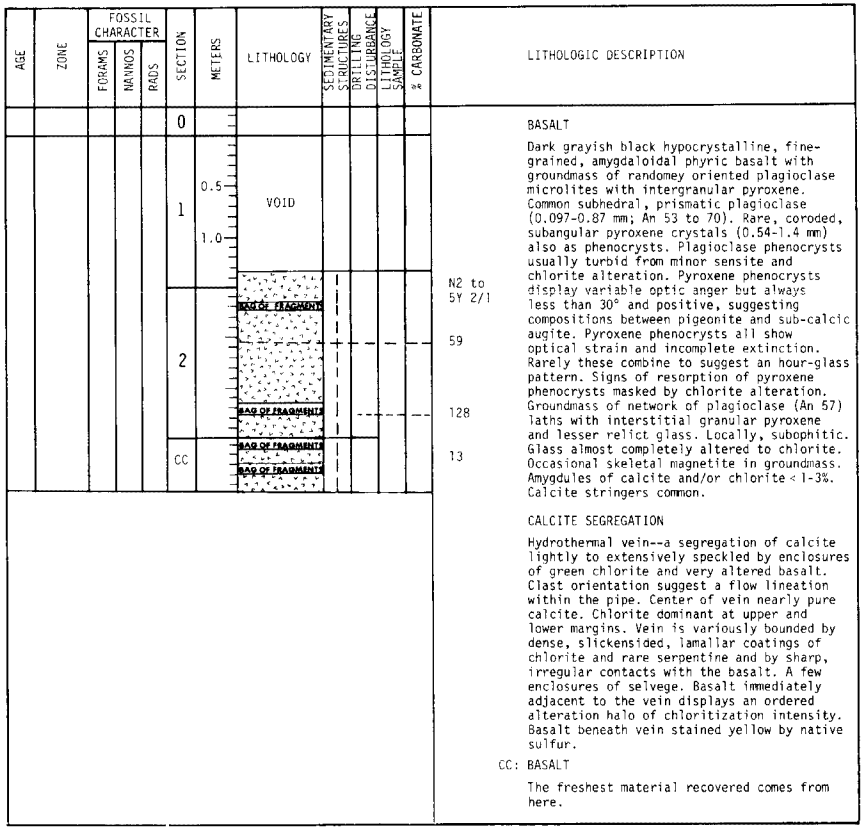
Hole 386 Core 66 Cored Interval: 964.2-973.8 m



BASALT

Dark grayish black hypocrystalline, fine-grained, amygdaloidal phyric basalt with groundmass of randomey oriented plagioclase microlites with intergranular pyroxene. Common subhedral, prismatic plagioclase (0.097-0.87 mm; An 53 to 70). Rare, coroded, subangular pyroxene crystals (0.54-1.4 mm) also as phenocrysts. Plagioclase phenocrysts usually turbid from minor sensite and chlorite alteration. Pyroxene phenocrysts display variable optic anger but always less than 30° and positive, suggesting compositions between pigeonite and sub-calcic augite. Pyroxene phenocrysts all show optical strain and incomplete extinction. Rarely these combine to suggest an hour-glass pattern. Signs of resorption of pyroxene phenocrysts masked by chlorite alteration. Groundmass of network of plagioclase (An 57) laths with interstitial granular pyroxene and lesser relict glass. Locally, subophitic. Glass almost completely altered to chlorite. Occasional skeletal magnetite in groundmass. Amygdules of calcite and/or chlorite < 1-3%. Calcite stringers common.

CALCITE SEGREGATION

Hydrothermal vein--a segregation of calcite lightly to extensively speckled by enclosures of green chlorite and very altered basalt. Clast orientation suggest a flow lineation within the pipe. Center of vein nearly pure calcite. Chlorite dominant at upper and lower margins. Vein is variously bounded by dense, slickensided, lamallar coatings of chlorite and rare serpentine and by sharp, irregular contacts with the basalt. A few enclosures of selvege. Basalt immediately adjacent to the vein displays an ordered alteration halo of chloritization intensity. Basalt beneath vein stained yellow by native sulfur.

CC: BASALT

DEEP SEA DRILLING PROJECT

LEG 43 SITE 387

SITE SUMMARY SHEET

POSITION: Latitude: 32°19.2'N Longitude: 67°40'W

Water depth (sea level): 5117 corrected meters, echo sounding

Bottom felt at: 5128 meters, drill pipe Penetration: 794.5 meters

Number of holes: 1 Number of cores: 50

Total length of cored section: 467.9 meters

Total core recovered: 178.2 meters

OLDEST SEDIMENT CORED:

Depth subbottom: 791.6 meters Nature: Limestone

Age: U. Berriasian-L. Valanginian Measured velocity: 2.77-3.88 km/s

BASEMENT:

Depth subbottom: 791.6-794.5 meters Nature: Basalt

Velocity range: 4.59-498 km/s

PRINCIPAL RESULTS:

Site 387 penetrated 791.6 meters of sediment and 2.9 meters of basalt. Eight major lithologic units and their approximate subbottom depths are (1) Pleistocene clay and zeolitic clay (0->42 m); (2) upper Oligocene to middle Eocene radiolarian mud (98-175 m); (3) middle Eocene to lower Paleocene siliceous turbidites, silicified claystones, rad mudstone, and chert (175-444 m); (4) Maestrichtian marly chalk (444-469 m); (5) lower Maestrichtian-upper Campanian multicolored claystone (469-479 m); (6) middle Cenomanian/Turonian to Aptian green-gray and black claystone and rad mudstone (479-584 m); (7) lower Barremain-upper Hauterivian to upper Berriasian-lower Valanginian chalk and limestone (584-791.9 m); and (8) hypocrystalline phyric basalt (>791.9 m).

As at Site 386, a hiatus of about 5 m.y. between the lower upper and lower middle Eocene was preceded by an interval of extremely rapid

sedimentation (100 m/m.y. or greater) of upper lower to lower middle Eocene siliceous claystones. During Cenomanian to Maestrichtian time black to gray claystones, interbedded with only minor multicolored claystones near the top, were deposited at Site 387, while Site 386 higher on the Bermuda Rise received multicolored claystones. This may mean only the deepest part of the basin (i.e. Site 387) was stagnant during this period or that Site 387 was receiving more organic material from productive surface waters. Sedimentation rates of 15-20 m/m.y. for the limestone unit are typical for a ridge crest environment.

Acoustic reflectors A, A*, and BETA are correlated with tops of (a) middle Eocene cherts, (b) middle Maestrichtian red claystone, and (c) Neocomian limestone, respectively. The contact between the green/black claystones and adjacent units is gradational; scattered carbon-rich layers occur in the underlying limestones and in the overlying Maestrichtian to Paleocene sediments. The beginning of the most extensive black clay deposition may coincide with uplift of the M.A.R. crest at the end of "Keathley time" (Aptian-Barremian) and consequent reduced deep circulation.

Calcareous clay directly overlying the basalt dates anomaly M-15/M-16 of the Keathley Sequence (M-Series) as upper Berriasian/lower Valanginian. If the basalt was intrusive it was probably emplaced very close to the contemporary mid-Atlantic Ridge crest.

CLAYSTONE with silicified interbeds (porcellanite) and calcareous claystone in the Section 1. Alternating color layers without distinct textural changes: mainly ε and δ subunits are developed with minor β (light, mottled) and ε (laminated). In Sections 4-5 units are indistinct due to intense drilling disturbance and whimsical color variations.
Dominant colors for "ε" subunits are: greenish gray (5G 5/2, 5G 4/2) - in the upper part (Sections 1-2); pale brownish green to greenish brown (5Y 5/2) and light brown (5YR 5/4) - in the lower (Sections 3-5). For "γ" subunits (homogeneous): light greenish gray (5G 7/1) - in the Section 1, grayish green (10GY 6/2), dusky yellow green (5GY 5/2), pale olive (10Y 6/2) - in the lower part.

RADIOLARIAN MUDSTONE with distinct rhythmic stratification (units: ε to β):
ε - dark, greenish gray (5GY 4/1) or grayish green (10GY 4/2); in the uppermost unit (Section 1) top layer is olive brown (5Y 4/4) to moderate brown (5YR 4/4) with green interbeds.
δ - poorly developed mottled zone (below ε) greenish gray
γ - well developed thick subunits, homogeneous, grayish green (10GY 5/2) or olive gray (5Y 3/2) in the upper part of the core; higher CaCO3
β - thin, faintly laminated grayish green; well developed only in Section 2, 60-80, (with silicified Foram-Rad mudstone basal layer).

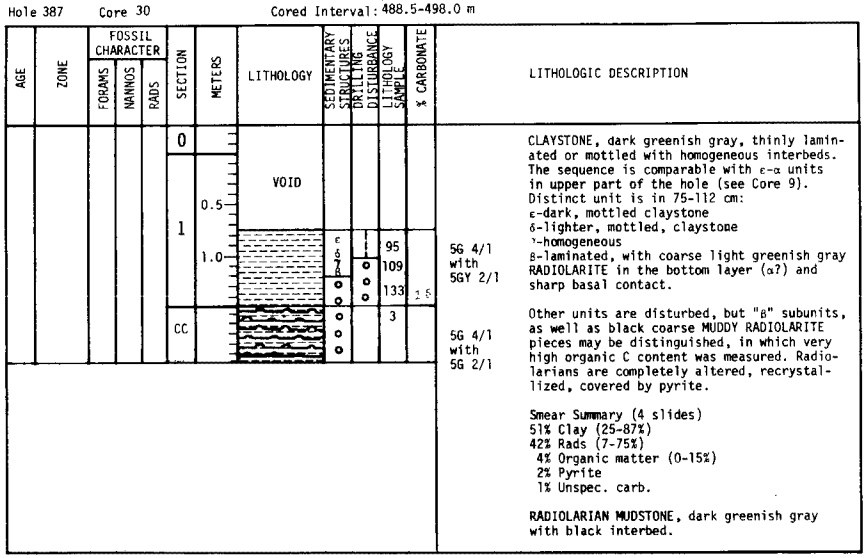
Hole 387 Core 30 Cored Interval: 488.5-498.0 m



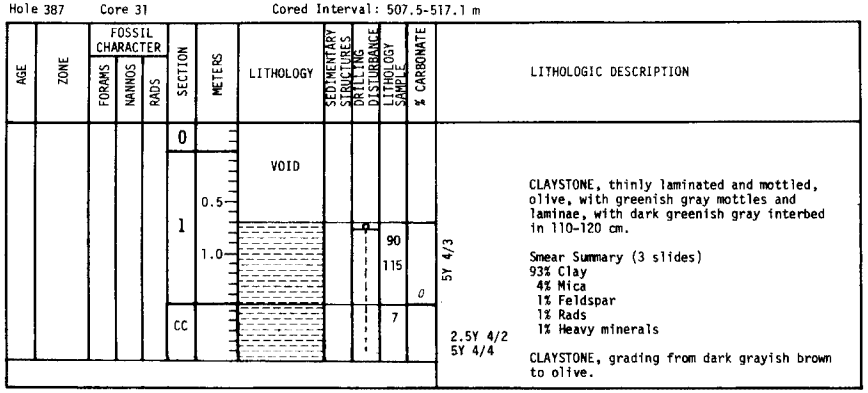
CLAYSTONE, dark greenish gray, thinly laminated or mottled with homogeneous interbeds. The sequence is comparable with ε-α units in upper part of the hole (see Core 9). Distinct unit is in 75-112 cm:
ε-dark, mottled claystone
δ-lighter, mottled, claystone
γ-homogeneous
β-laminated, with coarse light greenish gray RADIOLARITE in the bottom layer (α?) and sharp basal contact.

Other units are disturbed, but "β" subunits, as well as black coarse MUDDY RADIOLARITE pieces may be distinguished, in which very high organic C content was measured. Radiolarians are completely altered, recrystallized, covered by pyrite.

Smear Summary (4 slides)
51% Clay (25-87%)
42% Rads (7-75%)
4% Organic matter (0-15%)
2% Pyrite
1% Unspec. carb.

RADIOLARIAN MUDSTONE, dark greenish gray with black interbed.

Hole 387 Core 31 Cored Interval: 507.5-517.1 m

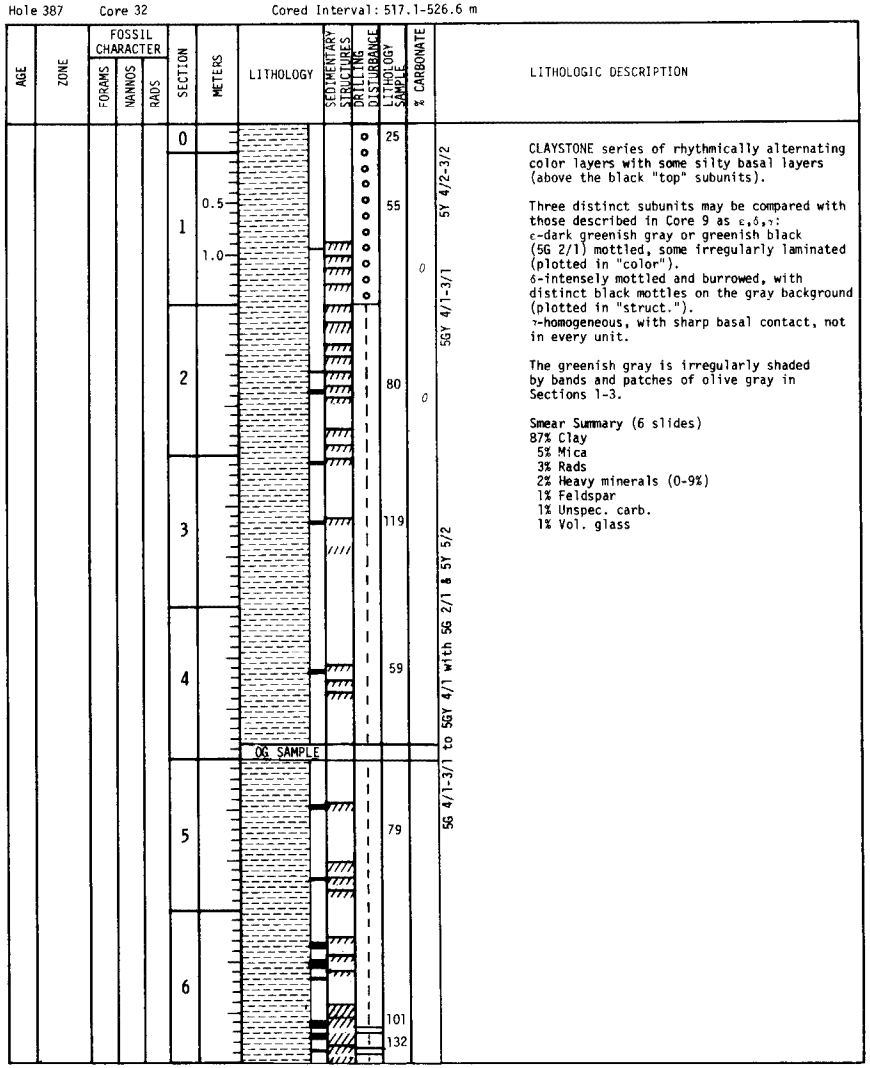


CLAYSTONE, thinly laminated and mottled, olive, with greenish gray mottles and laminae, with dark greenish gray interbed in 110-120 cm.

Smear Summary (3 slides)
93% Clay
4% Mica
1% Feldspar
1% Rads
1% Heavy minerals

CLAYSTONE, grading from dark grayish brown to olive.

Hole 387 Core 32 Cored Interval: 517.1-526.6 m



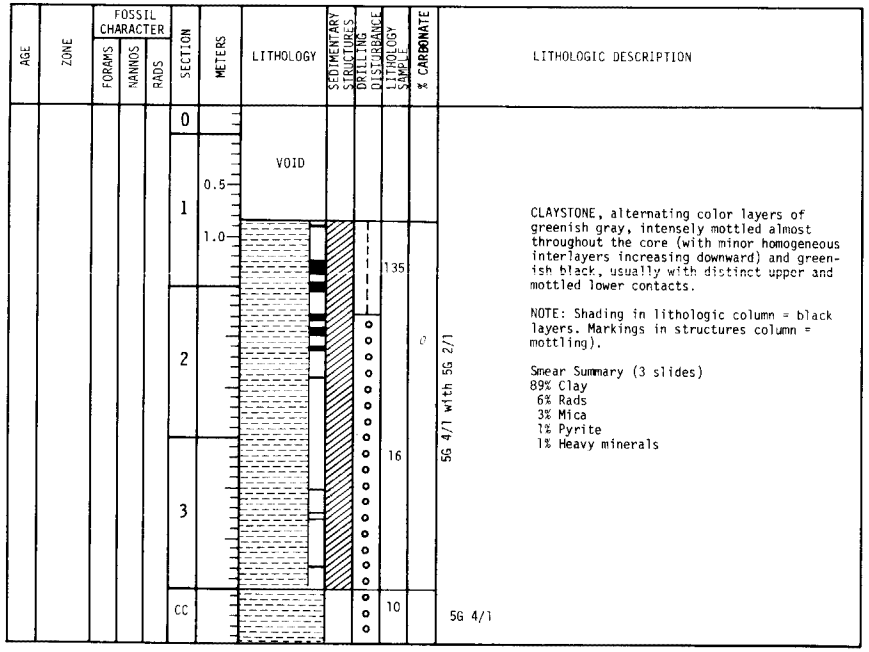
CLAYSTONE series of rhythmically alternating color layers with some silty basal layers (above the black "top" subunits).

Three distinct subunits may be compared with those described in Core 9 as ε,δ,γ:
ε-dark greenish gray or greenish black (5G 2/1) mottled, some irregularly laminated (plotted in "color").
δ-intensely mottled and burrowed, with distinct black mottles on the gray background (plotted in "struct.").
γ-homogeneous, with sharp basal contact, not in every unit.

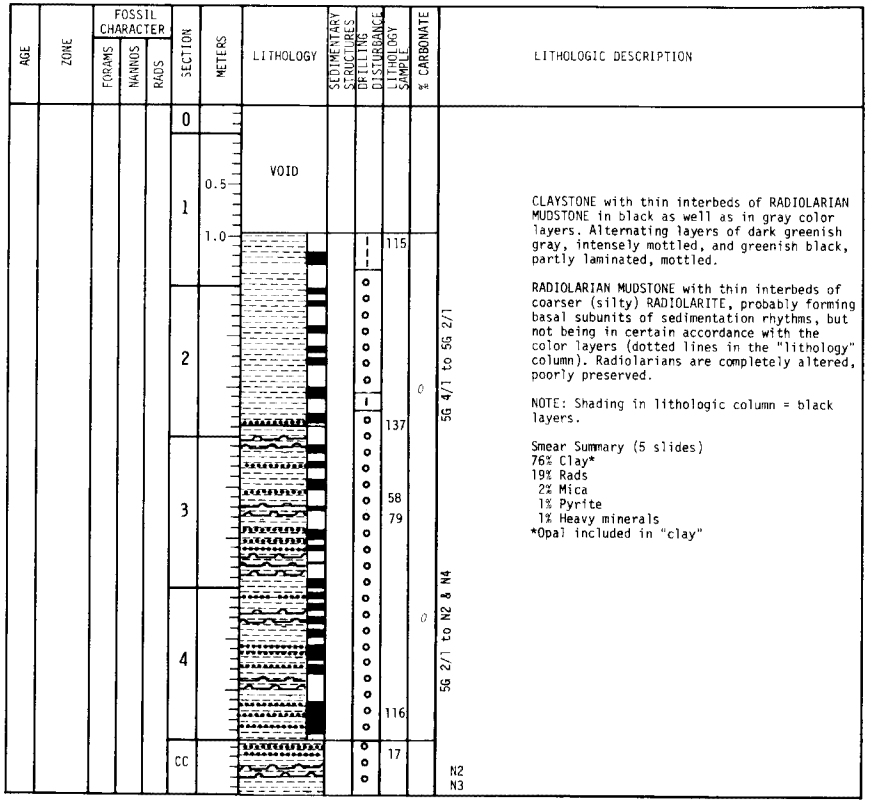
The greenish gray is irregularly shaded by bands and patches of olive gray in Sections 1-3.

Smear Summary (6 slides)
87% Clay
5% Mica
3% Rads
2% Heavy minerals (0-9%)
1% Feldspar
1% Unspec. carb.
1% Vol. glass

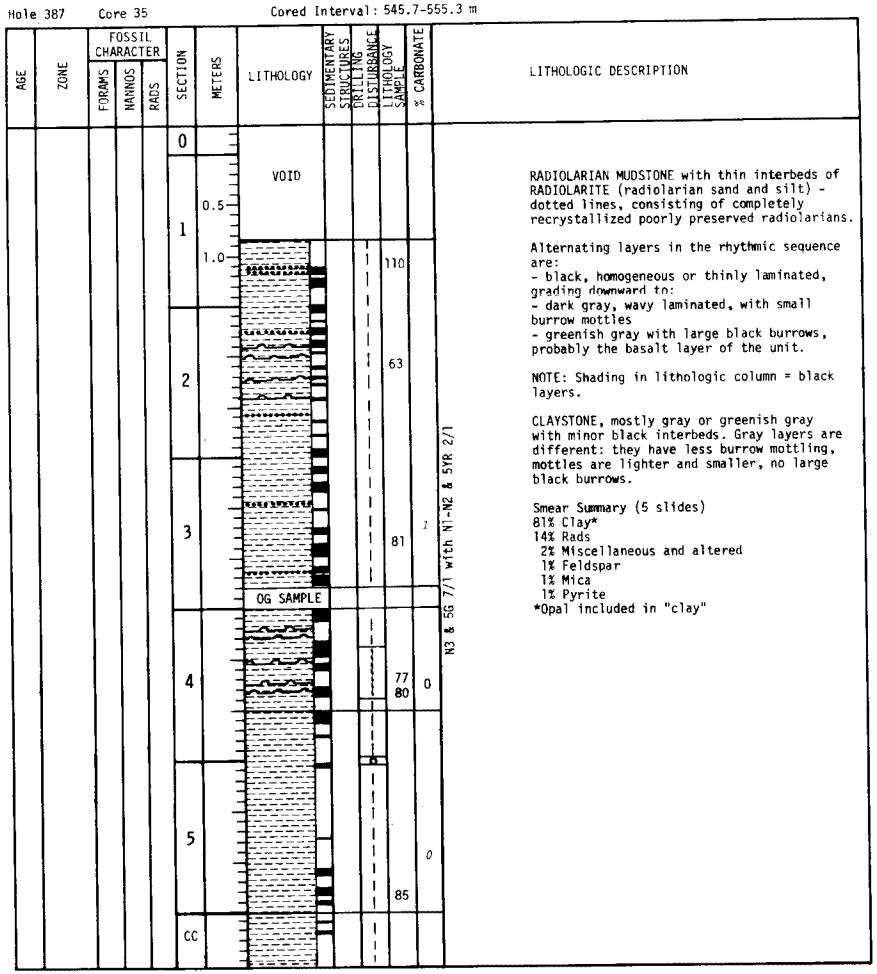
Hole 387 Core 33 Cored Interval: 526.6-536.2 m



Hole 387 Core 34 Cored Interval: 536.2-545.7 m



Hole 387 Core 35 Cored Interval: 545.7-555.3 m



RADIOLARIAN MUDSTONE with thin interbeds of RADIOLARITE (radiolarian sand and silt) - dotted lines, consisting of completely recrystallized poorly preserved radiolarians.

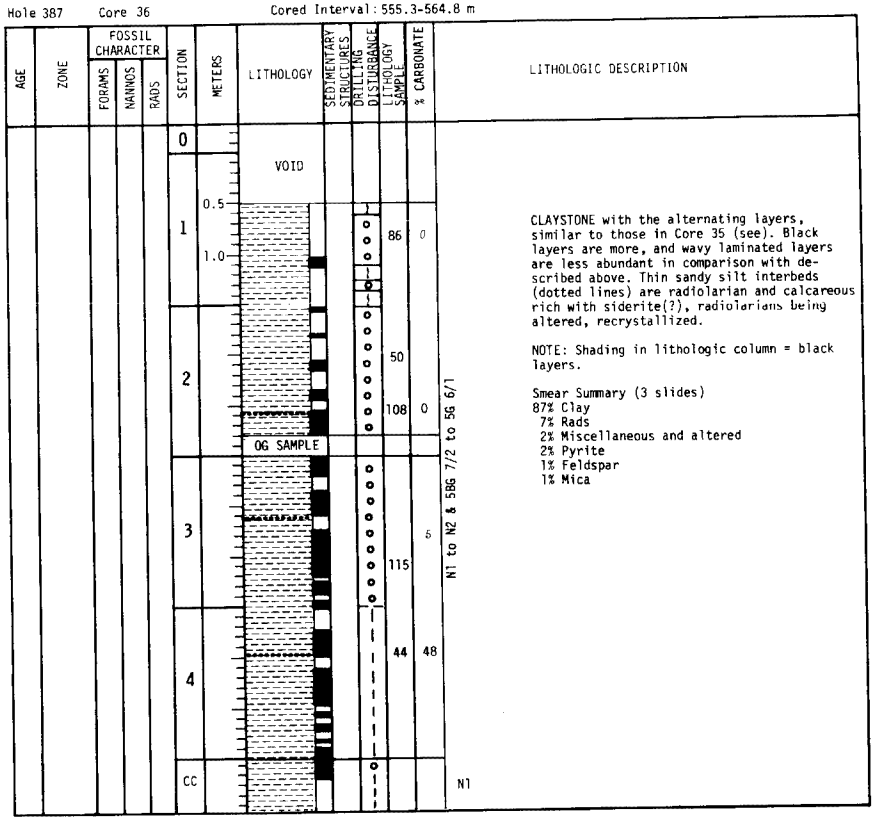
Alternating layers in the rhythmic sequence are:
- black, homogeneous or thinly laminated, grading downward to:
- dark gray, wavy laminated, with small burrow mottles
- greenish gray with large black burrows, probably the basalt layer of the unit.

NOTE: Shading in lithologic column = black layers.

CLAYSTONE, mostly gray or greenish gray with minor black interbeds. Gray layers are different: they have less burrow mottling, mottles are lighter and smaller, no large black burrows.

Smear Summary (5 slides)
81% Clay*
14% Rads
2% Miscellaneous and altered
1% Feldspar
1% Mica
1% Pyrite
*Opal included in "clay"

Hole 387 Core 36 Cored Interval: 555.3-564.8 m



CLAYSTONE with the alternating layers, similar to those in Core 35 (see). Black layers are more, and wavy laminated layers are less abundant in comparison with described above. Thin sandy silt interbeds (dotted lines) are radiolarian and calcareous rich with siderite(?), radiolarians being altered, recrystallized.

NOTE: Shading in lithologic column = black layers.

Smear Summary (3 slides)
87% Clay
7% Rads
2% Miscellaneous and altered
2% Pyrite
1% Feldspar
1% Mica

LITHOLOGIC DESCRIPTION

LIMESTONE, very light gray to SIDERITIC LIMESTONE, dark olive gray (5Y 3/1) with most shades in between. Alternating layers of homogeneous or burrowed limestone with laminated one and with dark, sideritic limestone, containing fine laminae, enriched by organic matter and pyrite.

Some pieces of chert appear, one with pyrite.

LITHOLOGIC DESCRIPTION

LIMESTONE with interbeds of MARLY (SIDERITIC) LIMESTONE grading to CALCAREOUS SIDERITIC MUDSTONE. Main kinds of the rocks in the rhythmic?) sequence are:
(1) Limestone - massive, burrowed, very light gray (N8 or 5B 8/1) with thin cherty(?) veinlets
(2) Limestone (to marly limestone) with minor siderite and pyrite, thinly laminated (rhythmic lamination with ≤1 cm thick micro-units). Wood fragments occur.
Grades to:
(3) Marly (sideritic) limestone, distinctly laminated with alternating dark greenish gray (5GY 4/1) and light (5GY 7/1) laminae (less than 1 mm thick)
(4) Calcareous sideritic mudstone (minor interbeds, shown as black in "Lithologic" column), dark greenish gray (5GY 4/1 to 3/1 or to 5Y 4/1), thinly laminated, with pyrite nodules.

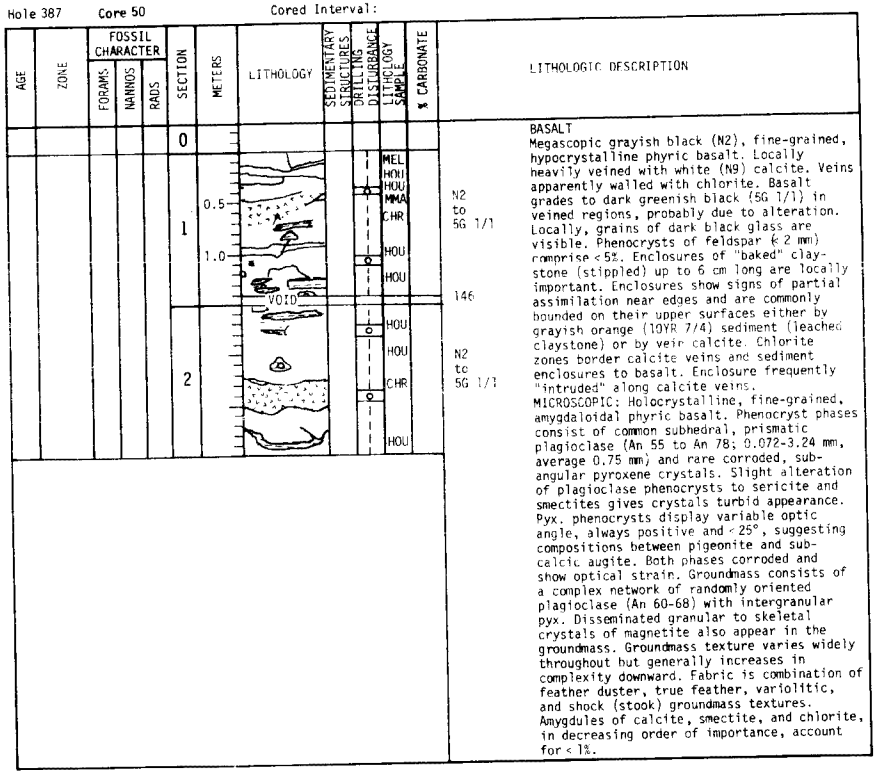
There are gradational transitions between (2)-(3)-(4) and sharp contacts (4)-(1). Some cherts occur in Sections 1, 2, 5, CC.

Smear Summary (8 slides)
55% Unspec. carb. (7-90%)
26% Clay (5-66%)
12% Siderite (5-20%)
6% Nannos (0-15%)
1% Mica

5GY 6/1-7/1 & 5GY 4/1-3/1 with N8, 5Y 4/1-5Y 6/1

40 cm

Hole 387 Core 50 Cored Interval:



BASALT

Megascopic grayish black (N2), fine-grained, hypocrystalline phyric basalt. Locally heavily veined with white (N9) calcite. Veins apparently walled with chlorite. Basalt grades to dark greenish black (5G 1/1) in veined regions, probably due to alteration. Locally, grains of dark black glass are visible. Phenocrysts of feldspar (≤ 2 mm) comprise < 5%. Enclosures of "baked" claystone (stippled) up to 6 cm long are locally important. Enclosures show signs of partial assimilation near edges and are commonly bounded on their upper surfaces either by grayish orange (10YR 7/4) sediment (leached claystone) or by vein calcite. Chlorite zones border calcite veins and sediment enclosures to basalt. Enclosure frequently "intruded" along calcite veins.

MICROSCOPIC: Holocrystalline, fine-grained, amygdaloidal phyric basalt. Phenocryst phases consist of common subhedral, prismatic plagioclase (An 55 to An 78; 0.072-3.24 mm, average 0.75 mm) and rare corroded, subangular pyroxene crystals. Slight alteration of plagioclase phenocrysts to sericite and smectites gives crystals turbid appearance. Pyx. phenocrysts display variable optic angle, always positive and < 25°, suggesting compositions between pigeonite and subcalcic augite. Both phases corroded and show optical strain. Groundmass consists of a complex network of randomly oriented plagioclase (An 60-68) with intergranular pyx. Disseminated granular to skeletal crystals of magnetite also appear in the groundmass. Groundmass texture varies widely throughout but generally increases in complexity downward. Fabric is combination of feather duster, true feather, variolitic, and shock (stook) groundmass textures. Amygdules of calcite, smectite, and chlorite, in decreasing order of importance, account for < 1%.
